(57) **ABSTRACT**
A surface cleaning apparatus comprises an air treatment member having a first end, a longitudinally spaced apart second end, an air inlet and an air outlet comprising an outlet conduit; an air flow path extending from a dirty air inlet to a clean air outlet and including a suction motor and the air treatment member; a pre-motor filter positioned in the air flow path downstream from the outlet conduit; and, an agitation member operatively engageable with the pre-motor filter.

SURFACE CLEANING APPARATUS**CROSS-REFERENCE TO RELATED APPLICATIONS**

This application is a continuation of U.S. patent application Ser. No. 13/781,559, filed Feb. 28, 2013, entitled Surface Cleaning Apparatus, the entirety of which is incorporated herein by reference.

FIELD

This specification relates to a surface cleaning apparatus. In a preferred embodiment, the surface cleaning apparatus has a filter wiping apparatus.

INTRODUCTION

The following is not an admission that anything discussed below is part of the prior art or part of the common general knowledge of a person skilled in the art.

Surface cleaning apparatus which utilize one or more cyclonic cleaning stages are known. Typically, a cyclone has an air inlet and an air outlet at the same end (e.g., the upper end). Dirt may accumulate in the other end (e.g., the bottom) of the cyclone chamber. Alternately, a dirt outlet may be provided in the bottom of the cyclone chamber so as to allow separated particulate matter to travel to a dirt collection chamber that is exterior to the cyclone chamber (see for example, US 2009/0205160). See also, US 2011/0314631, which discloses a cyclone chamber having an air inlet and an air outlet at one end and the end wall opposed to the end with the air inlet and the air outlet is spaced from the sidewall of the cyclone chamber by a variable amount so as to provide an outlet through which dirt may exit the cyclone chamber to an exterior dirt collection chamber.

SUMMARY

This summary is intended to introduce the reader to the more detailed description that follows and not to limit or define any claimed or as yet unclaimed invention. One or more inventions may reside in any combination or sub-combination of the elements or process steps disclosed in any part of this document including its claims and figures.

According to one broad aspect, a surface cleaning apparatus is provided with a uniflow cyclone chamber having a sidewall outlet. For example, the cyclone air inlet may be provided at a first end, the air outlet (e.g. vortex finder) may be provided at the second opposed end wall and a dirt outlet may be provided through a sidewall of the cyclone chamber at the second opposed end. For example, the dirt outlet may comprise an opening in the sidewall that extends radially around part of the sidewall of the cyclone chamber. The opening may be provided at the end wall of the cyclone chamber or it may be spaced therefrom (e.g., the sidewall may extend to the second opposed wall except at one location which defines a cut out or slot in the sidewall through which dirt may exit the cyclone chamber). Alternately, the sidewall may be spaced from the second opposed end wall so as to provide a gap (which may have a constant height or may have a variable height) through which dirt may exit the cyclone chamber. An advantage of this design is that a cyclone chamber having improved dirt separation efficiency is obtained. By enhancing the separation efficiency of the cyclone, a second stage cyclone may not be needed. In addition, removing an increased amount of

2

particulate matter from the airstream passing through the cyclone chamber reduces the amount of entrained particulate matter which will be conveyed to an optional pre-motor filter, thereby extending the lifetime of the pre-motor filter before washing or replacement is required.

Optionally, the end wall of the cyclone chamber at the air inlet end may be rounded. For example, the air inlet end of the cyclone chamber may be shaped similar to a horizontal section through a toroid. Accordingly, the rounded portion may extend towards the opposed second end so as to define part of the sidewall of the cyclone chamber.

Optionally, in such an embodiment, the air inlet end of the cyclone chamber is openable so as to allow access to the interior of the cyclone chamber. The inner end of the rounded portion may be part of the openable end wall of the cyclone chamber. For example, the rounded portion may abut a facing edge of the sidewall or it may seat against an inner surface of the sidewall. Such a construction is advantageous as it allows the rounded end wall to be emptied while providing an appropriate seal at the opening end of the cyclone chamber. It will be appreciated that, optionally, an exterior dirt collection chamber may be openable at the same end as a cyclone chamber and, in such a case, it is preferably openable concurrently with the cyclone chamber. For example, a common floor or end wall may be utilized to close both the cyclone chamber and the dirt collection chamber. In such a case, the end wall of the dirt collection chamber and the half toroidal shape of the lower end of the cyclone chamber may be molded as a single piece.

It will be appreciated by a person skilled in the art that any of the features relating to the openable end wall of the cyclone chamber discussed herein may not be utilized with the uniflow cyclone construction disclosed herein but may be used by itself or with any other feature disclosed herein.

In accordance with another embodiment, a pre-motor filter is provided. Preferably, the pre-motor filter is provided with a transparent housing on the upstream (dirty) side of the pre-motor filter. The transparent housing permits a user to see the upstream side of the pre-motor filter and determine when the pre-motor filter may require cleaning.

In another embodiment, the pre-motor filter may be provided in a filter holder and the filter holder may be removable from the surface cleaning apparatus for cleaning or replacement of the pre-motor filter. The filter holder may define a chamber in which particulate matter conveyed from the cyclone chamber to the pre-motor filter may be stored. This may include particulate matter that is dis-entrained as the air changes direction to travel through the pre-motor filter and/or particulate matter that is separated from the airflow as the airflow enters the pre-motor filter. For example, the filter holder may comprise a cup having a sidewall and an end wall. The pre-motor filter may be placed in the cup spaced from the end wall with the pre-motor filter abutting the sidewall so as to define a dirt cup chamber between the end wall of the cup and the side of the pre-motor filter facing the end wall. An air conduit (e.g. an extension of the vortex finder) may extend through the foam into the dirt cup chamber. Accordingly, air exiting the cyclone chamber may travel through the conduit into the dirt cup chamber to reach the upstream side of the pre-motor filter and then travel through the pre-motor filter. Dirt may accordingly accumulate on the upstream side of the pre-motor filter. Optionally, the conduit may extend into the dirt cup chamber to a height above that of the pre-motor filter such that particulate matter may not fall downwardly through the conduit into the cyclone chamber. In accordance with such an embodiment, the filter holder may be removed from the

surface cleaning apparatus and conveyed to a location (e.g. a sink or a garbage can) where the pre-motor filter may be removed so as to allow access to the dirt cup chamber so it may be emptied. Alternately, a portion of the dirt cup chamber may be openable. It will be appreciated that, in such an embodiment, the cup or at least the portion of a cup defining the dirt cup chamber may be transparent so as to allow a user to determine when the filter is dirty and/or the dirt cup chamber should be emptied.

Alternately, in some embodiments, the pre-motor filter may be positioned with the upstream side facing upwardly. Air may accordingly exit the cyclone chamber and travel, e.g., laterally through a duct to a position above the pre-motor filter. The air may then travel downwardly through the pre-motor filter. A sidewall may extend above the top of the pre-motor filter to define a dirt collection area. The portion of the duct or housing containing the pre-motor filter may be openable so as to allow access to the dirt collection area. When it is desired to remove dirt which has accumulated on top of the pre-motor filter, the duct or housing may be opened and the portion of the surface cleaning apparatus containing the pre-motor filter may be inverted to allow the dirt to be removed.

It will be appreciated by a person skilled in the art that any of the features of the pre-motor filter and pre-motor filter holder discussed herein need not be utilized with the uniflow cyclone design disclosed herein but may be used by themselves or in combination with any other feature disclosed herein.

In accordance with another embodiment, a pre-motor filter is provided with a pre-motor filter cleaner. For example, an agitation member may be provided to impact the pre-motor filter, preferably the upstream side thereof, so as to loosen dirt of the upstream side. The upstream side may then be emptied, e.g., by inverting the pre-motor filter (e.g. a pre-motor filter holder containing the pre-motor filter may be inverted thereby removing particular matter that has been loosened from the upstream side of the pre-motor filter). It will be appreciated that this feature is preferably used with the pre-motor filter dirt cup or dirt collection area discussed herein.

An advantage of this design is that the required amount of time between washing or replacing the pre-motor filter may be increased since the increase in back pressure caused by a dirty pre-motor filter may be reduced, particularly if the upstream side of the pre-motor filter faces downwardly. The cleaning member may be a mechanical or electro-mechanical member that taps, scrapes or otherwise engages the pre-motor filter to remove surface dirt therefrom. For example, a reciprocating motor with a hammer or the like provided on an arm extending therefrom may be utilized. The hammer may dislodge dirt from the upstream side when it contacts the pre-motor filter. Alternately, a weight, which is suspended on an arm at a position spaced from the pre-motor filter may be provided. Movement of the pre-motor filter may cause the weight to oscillate and engage repeatedly the pre-motor filter thereby assisting in cleaning the upstream side of the pre-motor filter. Alternately, one and more ribs or other scrapers may be provided abutting the upstream side and rotatably mounted so as to scrape the upstream surface thereby removing dirt therefrom.

It will be appreciated by a person skilled in the art that any of the features of the filter cleaning member disclosed herein need not be utilized with the uniflow cyclone design disclosed herein but may be used by itself or in combination with any other feature disclosed herein.

If a pre-motor filter is provided with a pre-motor filter dirt cup holder that receives dirt that accumulates on, or is dislodged from, the upstream side of the pre-motor filter, the surface cleaning apparatus may be constructed such that the pre-motor filter dirt cup may be emptied when the cyclone chamber and/or a dirt collection chamber in communication with the cyclone chamber is emptied. Preferably, the pre-motor filter dirt cup, the cyclone chamber and the dirt chamber in communication with the cyclone chamber are concurrently emptied. For example, all three dirt collection areas may have a common floor or wall which is openable.

The pre-motor filter dirt cup may comprise a chamber exterior to the cyclone chamber which is in communication with the upstream side of the pre-motor filter via an angled pathway (e.g., a ramp). For example, the upstream side of the pre-motor filter may face the air outlet end of the cyclone chamber so that the air exiting the cyclone chamber travels linearly to reach the pre-motor filter. An angled wall may be provided underneath the pre-motor filter and above the cyclone chamber so as to direct dirt to a dirt collection chamber adjacent, e.g., the sidewall of the cyclone chamber or the dirt collection chamber in communication with the cyclone chamber. The dirt cup and the cyclone chamber may have a common floor which is openable. In an alternate design, the upstream side of the pre-motor filter may face the vortex finder. A dirt collection chamber may be provided in an insert extending upwardly from the end wall of the cyclone chamber opposed to and facing the vortex finder. Accordingly, dirt may fall from the upstream side of the pre-motor filter and travel downwardly through the vortex finder to the pre-motor filter dirt collection chamber. In such a case, a filter cleaner as discussed previously may be provided and may engage the upstream side of the pre-motor filter. Accordingly, when a cyclone is not in use (e.g. the vacuum cleaner is turned off), the filter cleaning member may tap or otherwise physically agitate the pre-motor filter to loosen dirt which then falls downwardly through the vortex finder into the dirt collection chamber for the pre-motor filter. It will be appreciated that the dirt collection chamber for the pre-motor filter may be opened when the end wall of the cyclone chamber is opened so as to permit the cyclone chamber to be emptied.

It will be appreciated by a person skilled in the art that any of the features of the openable pre-motor filter dirt cup need not be utilized with the uniflow cyclone design disclosed herein but may be used by itself or in combination with any other feature disclosed herein.

Alternately, or in addition, it will be appreciated that the pre-motor filter dirt cup may be removable for emptying. The pre-motor filter dirt cup may be removable by itself, in combination with the cyclone chamber, in combination with the dirt chamber for the cyclone chamber or preferably, concurrently with both the cyclone chamber and the dirt collection chamber for the cyclone chamber. In particular, it is preferred that the dirt cup is removed with both the cyclone chamber and the dirt collection chamber and that all three are emptied at the same time. It will be appreciated by a person skilled in the art that any of the features of the removable pre-motor filter dirt cup need not be utilized with the uniflow cyclone design disclosed herein but may be used by itself or in combination with any other features disclosed herein.

In another embodiment, the surface cleaning apparatus may include an expandable hose which is biased to the extended position and is stored in a contracted position in the surface cleaning apparatus. An advantage of this design is that the suction hose may be stored in the surface cleaning

apparatus and may be deployed when needed. For example, the hose may be stored in a compartment which has a hose outlet. One and more rollers, preferably at least a pair of opposed rollers or drive wheels, may be provided on opposed sides of the hose. The rollers may be manually and, preferably, electrically operated. Rotation of the rollers in one direction may allow the hose to be withdrawn from the chamber. Rotation of the rollers in the opposite direction may draw the hose automatically into the chamber for storage. In an alternate design, a ratchet type mechanism may be used. For example, a pair of pivotally mounted arms which are biased to an engagement position may be provided. The arms are positioned so as to contact the hose in an engaged position and prevent the hose from expanding and being drawn out of the chamber. If it is desired to remove the hose from the chamber, the arms may be moved to a disengaged position thereby allowing the hose to automatically extend itself due to the compression of the hose in the chamber. When it is desired to retract the hose into the chamber, the hose may be manually inserted, thereby compressing the hose in the chamber, or a pair of rollers or other motorized means may draw the hose into the chamber. It will be appreciated by a person skilled in the art that any of the features of a hose that is biased to an extended position need not be utilized with the uniflow cyclone design as disclosed herein but may be used by itself or in combination with any other feature disclosed herein.

In one embodiment, there is provided a surface cleaning apparatus comprising:

- (a) a body housing a suction motor;
- (b) a uniflow cyclone chamber comprising a first end having a first end wall, a second opposed end having a second end wall, a sidewall, an air inlet in the first end, a dirt outlet in the second end and an air outlet that is configured so that air exits the cyclone chamber through the second end;
- (c) a dirt collection chamber exterior to the cyclone chamber; and,
- (d) an air flow path extending from a dirty air inlet to a clean air outlet and including the suction motor and the cyclone chamber.

In some embodiments, the cyclone chamber may have a longitudinal axis and the dirt outlet is oriented generally parallel to the longitudinal axis.

In some embodiments, the sidewall may extend to the second end and the dirt outlet is provided in the sidewall.

In some embodiments, the first end may comprise a lower end.

In some embodiments, the dirt outlet may have a radial extent and may have an upstream end and a downstream end based on the direction of airflow in the cyclone chamber and the upstream end may be located from 0-90 degrees downstream from the air inlet.

In some embodiments, the upstream end may be located from 0-45 degrees downstream from the air inlet.

In some embodiments, the upstream end may be located from 0-15 degrees downstream from the air inlet.

In some embodiments, the downstream end may be located from 5-150 degrees downstream from the upstream end.

In some embodiments, the downstream end may be located from 15-120 degrees downstream from the upstream end.

In some embodiments, the downstream end may be located from 35-75 degrees downstream from the upstream end.

In some embodiments, the dirt outlet may have a radial extent and may have an upstream end and a downstream end based on the direction of airflow in the cyclone chamber and the downstream end may be located from 5-150 degrees downstream from the upstream end.

In some embodiments, the downstream end may be located from 15-120 degrees downstream from the upstream end.

In some embodiments, the downstream end may be located from 35-75 degrees downstream from the upstream end.

In some embodiments, the dirt collection chamber may partially surround the cyclone chamber.

In some embodiments, the dirt outlet may have a radial extent and may have an upstream end and a downstream end based on the direction of airflow in the cyclone chamber and the upstream end may be located proximate a location at which a sidewall of the dirt collection chamber extends outwardly from the sidewall of the cyclone chamber.

In some embodiments, the dirt collection chamber may partially surround the cyclone chamber and the upstream end may be located proximate a location at which a sidewall of the dirt collection chamber extends outwardly from the sidewall of the cyclone chamber.

In some embodiments, the dirt collection chamber may partially surround the cyclone chamber and the upstream end may be located proximate a location at which a sidewall of the dirt collection chamber extends outwardly from the sidewall of the cyclone chamber.

In some embodiments, the dirt collection chamber may partially surround the cyclone chamber and the upstream end may be located proximate a location at which a sidewall of the dirt collection chamber extends outwardly from the sidewall of the cyclone chamber.

In some embodiments, the dirt collection chamber may surround the cyclone chamber, the dirt outlet may have a radial extent and may have an upstream end and a downstream end based on the direction of airflow in the cyclone chamber and the upstream end may be located from 0-90 degrees upstream from a location at which a sidewall of the dirt collection chamber is closest to the sidewall of the cyclone chamber.

In some embodiments, the upstream end may be located proximate the location at which a sidewall of the dirt collection chamber is closest to the sidewall of the cyclone chamber.

It will be appreciated by a person skilled in the art that a surface cleaning apparatus may embody any one or more of the features contained herein and that the features may be used in any particular combination or sub-combination.

DRAWINGS

The drawings included herewith are for illustrating various examples of articles, methods, and apparatuses of the teaching of the present specification and are not intended to limit the scope of what is taught in any way.

FIG. 53 is a cross sectional view of another embodiment of a portion of a surface cleaning apparatus;

FIG. 54 is a cross sectional view of an alternate configuration of the portion of the surface cleaning apparatus of FIG. 53;

FIG. 55 is a cross sectional view of another embodiment of a portion of a surface cleaning apparatus; and,

FIG. 56 is a cross sectional view of an alternate configuration of the portion of the surface cleaning apparatus of FIG. 55;

DETAILED DESCRIPTION

Various apparatuses or processes will be described below to provide an example of an embodiment of each claimed invention. No embodiment described below limits any claimed invention and any claimed invention may cover processes or apparatuses that differ from those described below. The claimed inventions are not limited to apparatuses or processes having all of the features of any one apparatus or process described below or to features common to multiple or all of the apparatuses described below. It is possible that an apparatus or process described below is not an embodiment of any claimed invention. Any invention disclosed in an apparatus or process described below that is not claimed in this document may be the subject matter of another protective instrument, for example, a continuing

patent application, and the applicants, inventors or owners do not intend to abandon, disclaim or dedicate to the public any such invention by its disclosure in this document.

General Description of a Canister Vacuum Cleaner

Referring to FIG. 1, a first embodiment of a surface cleaning apparatus 1 is shown. In the embodiment shown, the surface cleaning apparatus is a canister-type vacuum cleaner. In alternate embodiments, the surface cleaning apparatus may be another suitable type of surface cleaning apparatus, such as an upright-style vacuum cleaner, and hand vacuum cleaner, a stick vac, a wet-dry type vacuum cleaner, a carpet extractor or the like.

In the illustrated example, the surface cleaning apparatus 1 includes a chassis portion or support structure 2 and a surface cleaning head 3. A surface cleaning unit 4 is mounted on the chassis portion 2. The surface cleaning apparatus 1 also has at least one dirty air inlet 5, at least one clean air outlet 6, and an air flow path or passage extending therebetween. In the illustrated example, the air flow path includes at least one flexible air flow conduit member (such as a hose 7 or other flexible conduit). Alternatively, the air flow path may be formed from rigid members.

At least one suction motor and at least one air treatment member are positioned in the air flow path to separate dirt and other debris from the airflow. Preferably, the chassis portion and/or surface cleaning unit include the suction motor, to draw dirty air in through the dirty air inlet, and the air treatment member to remove dirt or debris from the dirty air flow. The air treatment member may be any suitable air treatment member, including, for example, one or more cyclones, filters, and bags. Preferably at least one air treatment member is provided upstream from the suction motor. Referring to FIGS. 2 and 3, in the illustrated example, the surface cleaning unit includes both the suction motor 8, in a motor housing 12 and an air treatment member in the form of a cyclone bin assembly 9. The motor housing can include at least one removable or openable door or grill 13 which may allow a user to access the interior of the motor housing 12, for example to access the motor 8, a post motor filter (e.g., a HEPA filter) or any other component within the housing 12. Preferably, as exemplified in FIG. 10, a cyclone bin assembly 9 is provided wherein the cyclone bin assembly comprises a cyclone chamber 10 and a dirt collection chamber 11.

Optionally, the surface cleaning unit 4 may be a portable surface cleaning unit and may be detachable from the chassis portion (FIG. 3). In such embodiments, the surface cleaning unit 4 includes a suction motor and is removably mounted to chassis portion 2. For example, chassis portion 2 may be connected to surface cleaning unit 4 by a mount apparatus 14 that allows the surface cleaning unit 4 to be detached from the chassis portion 2. Preferably, mount apparatus 14 has a release actuator that is foot operable, such as a foot pedal. The foot pedal may be lined electrically or mechanically to a surface cleaning unit engagement member, which may comprise one or more engagement members configured to engage and retain surface cleaning unit 4 in position on chassis portion 2. For example, referring to FIGS. 6 and 7, in the illustrated embodiment the mount apparatus 14 includes a foot pedal 145 that is connected to rear latch 146 and to front latch 147 via a connecting rod 148. The rear latch 146 engages a rear slot 149 on the surface cleaning unit 4, and the front latch 147 engages a corresponding front slot 150. Stepping on the pedal 145 can disengage both latches 146, 147, thereby releasing the surface cleaning unit 4 from the chassis portion 2. The latches 146, 147 and pedal 145 can be biased toward the

latched configuration. Optionally, a cavity 152 for storing an auxiliary cleaning tool 153 may be formed at the interface between the surface cleaning unit 4 and the chassis 2 and preferably comprises a recess in the lower surface of the surface cleaning unit 4.

In the embodiment shown, the surface cleaning head 3 includes the dirty air inlet 5 in the form of a slot or opening formed in a generally downward facing surface of the surface cleaning head 3. From the dirty air inlet 5, the air flow path extends through the surface cleaning head 3, and through an up flow conduit 16 (FIG. 2) in the chassis portion 2 to the surface cleaning unit 4. In the illustrated example, the clean air outlet 6 is provided in the rear of the surface cleaning unit 4, and is configured to direct the clear air in a generally lateral direction, toward the back of the apparatus 1.

A handle 17 is provided toward the top of the up flow conduit 16 to allow a user to manipulate the surface cleaning head 3. Referring to FIGS. 1 and 3, the up flow conduit 16 extends along an upper axis 18 and is moveably mounted to the surface cleaning head 3. In the illustrated example, the up flow conduit 16 is pivotally mounted to the surface cleaning head via a pivot joint 19. The pivot joint 19 may be any suitable pivot joint. Alternatively, or in addition to being pivotally coupled to the surface cleaning head, the up flow conduit 16 can also be rotatably mounted to the surface cleaning head. In this configuration, the up flow conduit 16 may be rotatable about the upper axis. In this configuration, rotation of the up flow conduit 16 about the upper axis may help steer the surface cleaning head across the floor (or other surface being cleaned). It will be appreciated that the surface cleaning head 3 and conduit 16 may be of any design known in the art and the air flow path to the surface cleaning unit 4 may be of any design.

Portable Cleaning Mode

In one aspect of the teachings described herein, which may be used in combination with any one or more other aspects, the vacuum cleaner 1 may be operable in a variety of different functional configurations or operating modes. The versatility of operating in different operating modes may be achieved by permitting the surface cleaning unit to be detachable from the chassis portion. Alternatively, or in addition, further versatility may be achieved by permitting portions of the vacuum cleaner to be detachable from each other at a plurality of locations in the chassis portion, and re-connectable to each other in a variety of combinations and configurations.

In the example illustrated, mounting the surface cleaning unit 4 on the chassis portion 2 allows the chassis portion 2 to carry the weight of the surface cleaning unit 4 and to, e.g., rollingly support the weight using rear wheels 100 and front wheel 101 (FIG. 2). With the surface cleaning unit 4 attached, the vacuum cleaner 1 may be operated like a traditional canister-style vacuum cleaner.

Alternatively, in some cleaning situations the user may preferably detach the surface cleaning unit 4 from the chassis portion 2 and choose to carry the surface cleaning unit 4 (e.g. by hand or by a strap) separately from the chassis portion 2, while still using the up flow conduit 16 to drivingly maneuver the surface cleaning head 3. When the surface cleaning unit 4 is detached, a user may more easily maneuver the surface cleaning head and the cleaning unit 4 around obstacles, like furniture and stairs.

To enable the vacuum suction generated by the surface cleaning unit 4 to reach the surface cleaning head 3 when the surface cleaning unit 4 is detached from the support structure 2, the airflow connection between the surface cleaning

11

head **3** and the cleaning unit **4** is preferably at least partially formed by a flexible conduit, such as the flexible hose **7**. The flexible conduit is preferably attached to the surface cleaning unit **4** and not chassis **2** so as to allow a user to detach the surface cleaning unit **4** and maintain a flow connection between the portable surface cleaning unit **4** and the surface cleaning head **3** without having to reconfigure or reconnect any portions of the airflow conduit **16** (FIG. **5**).

Referring to FIG. **5**, when the surface cleaning apparatus **1** is in use, a user may detach the surface cleaning unit **4** from the chassis portion **2** without interrupting the airflow communication between the cleaning unit **4** and the surface cleaning head **3**. This allows a user to selectively detach and re-attach the cleaning unit **4** to the support structure **2** during use without having to stop and reconfigure the connecting hoses **7** or other portions of the airflow conduit **16**.

Removable Cyclone Bin Assembly

The following is a description of a removable cyclone bin assembly that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Optionally, the cyclone bin assembly **9** can be detachable from the motor housing **12**. Providing a detachable cyclone bin assembly **9** may allow a user to carry the cyclone bin assembly **9** to a garbage can for emptying, without needing to carry or move the rest of the surface cleaning apparatus **1**. Preferably, the cyclone bin assembly **9** can be separated from the motor housing **12** while the surface cleaning unit **4** is mounted on the chassis portion **2** and also when the surface cleaning unit **4** is separated from the chassis portion **2**. Accordingly, the cyclone bin assembly is preferably positioned on an upper portion of the surface cleaning unit **4** and may be mounted on a shelf or recess provided forwardly of the suction motor.

Preferably, as exemplified in FIG. **3**, the cyclone bin assembly **9** is removable as a closed module, which may help prevent dirt and debris from spilling out of the cyclone bin assembly **9** during transport.

In the illustrated example, the cyclone bin assembly **9** includes an outer sidewall **35** and a lid **36**. The lid **36** is openable, and in the illustrated embodiment is pivotally connected to the sidewall **35** by hinges **102** (FIG. **9**) and pivotal between an open position (FIG. **12**) and a closed position (FIG. **9**). The lid **36** can be held in its closed position using any suitable closure member, such as releasable latch **103**.

In the illustrated embodiment, a bin handle **37** is provided on the lid **36**. The bin handle **37** may allow a user to carry the surface cleaning unit **4** when it is detached from the chassis portion **2**, and preferably is removable from the suction motor housing **12** with the cyclone bin assembly **9** so that it can also be used to carry the cyclone bin assembly for emptying.

Cyclone Construction

The following is a description of a cyclone construction that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Referring to FIGS. **11** and **13** in the illustrated embodiment the cyclone chamber **10** extends along a cyclone axis **38** and includes a first end wall **39**, a second end wall **40** axially spaced apart from the first end wall **39** and a generally cylindrical sidewall **41** extending between the first and second end walls **39**, **40**. Optionally, some or all of the cyclone walls can coincide with portions of the dirt collection chamber **11** walls, suction motor housing **12** walls and/or may form portions of the outer surface **35** of surface

12

cleaning unit. Alternatively, in some examples some or all of the cyclone walls can be distinct from other portions of the surface cleaning unit. In the illustrated embodiment, the cyclone chamber **10** is arranged in a generally vertical, uniflow cyclone configuration. Alternatively, the cyclone chamber can be provided in another configuration, including, having at least one or both of the air inlet and air outlet positioned toward the top of the cyclone chamber, or as a horizontal or inclined cyclone.

In the illustrated embodiment, the cyclone chamber **10** includes a cyclone air inlet **42** in fluid communication with a cyclone air outlet **43**. The cyclone chamber **10** also includes at least one dirt outlet **44** (see also FIG. **10**), through which dirt and debris that is separated from the air flow can exit the cyclone chamber **10**. While it is preferred that most or all of the dirt exit the cyclone chamber via the dirt outlet, some dirt may settle on the bottom end wall of the cyclone chamber **10** and/or may be carried with the air exiting the cyclone chamber via the air outlet **43**.

Preferably the cyclone air inlet **42** is located toward one end of the cyclone chamber **10** (the lower end in the example illustrated) and may be positioned adjacent the corresponding cyclone chamber end wall **40**. Alternatively, the cyclone air inlet **42** may be provided at another location within the cyclone chamber **10**.

Referring to FIG. **11**, in the illustrated embodiment the air inlet **42** includes an upstream or inlet end **45**, which may be coupled to the hose **7** or other suitable conduit, and a downstream end **46** (FIG. **10**) that is spaced apart from the upstream end **45**. In the illustrated configuration, the cyclone bin assembly **9** can be removed from the surface cleaning unit **4**, for example, for cleaning or emptying, while the hose **7** remains with the surface cleaning unit **4**. This may allow a user to remove the cyclone bin **9** assembly without having to detach or decouple the hose **7**. Alternatively, the downstream end of the hose **7** may be coupled to the cyclone bin assembly **9** such that the downstream end of the hose travels with the cyclone bin assembly when it is removed.

The air inlet **42** defines an inlet axis **47** and has an inlet diameter **48** (FIG. **13**). The cross-sectional area of the air inlet **42** taken in a plane orthogonal to the inlet axis **47** can be referred to as the cross-sectional area or flow area of the air inlet **42**. Preferably, the air inlet **42** is positioned so that air flowing out of the downstream end is travelling generally tangentially relative to the sidewall **41** of the cyclone chamber **10**.

The perimeter of the air inlet **42** defines a cross-sectional shape of the air inlet. The cross-sectional shape of the air inlet can be any suitable shape. In the illustrated example the air inlet has a generally round/circular cross-sectional shape with radius **48**. Optionally, the diameter **48** may be between about 0.25 inches and about 5 inches or more, preferably between about 1 inch and about 5 inches, more preferably is between about 0.75 and 2 inches or between about 1.5 inches and about 3 inches, and most preferably is about 2 to 2.5 inches or between about 1 to 1.5 inches. Alternatively, instead of being circular, the cross-sectional shape of the air inlet may be another shape, including, for example, oval, square and rectangular.

Air can exit the cyclone chamber **10** via the air outlet **43**. Optionally, the cyclone air outlet **43** may be positioned in one of the cyclone chamber end walls, and in the example illustrated is positioned in the end wall **39**, at the opposite end of the cyclone chamber **10** from the air inlet **42**. In this configuration, air can enter at the bottom of the cyclone chamber **10** and exit at the upper end of the cyclone chamber **10**.

In the illustrated example, the cyclone air outlet **43** includes a vortex finder **49**. In the example illustrated, the longitudinal cyclone axis **38** is aligned with the orientation of the vortex finder **49**. In the illustrated embodiment the air outlet **43** is generally circular in cross-sectional shape and defines an air outlet diameter **51** (FIG. **21**). Optionally, the cross-sectional or flow area of the cyclone air outlet **43** may be between about 50% and about 150% and between about 60%-90% and about 70%-80% of the cross-sectional area of the cyclone air inlet **42**, and preferable is generally equal to the cyclone air inlet area. In this configuration, the air outlet diameter **51** may be about the same as the air inlet diameter **48**.

Referring to FIG. **11**, in the illustrated embodiment, the upper end wall **39** is connected to the upper end of the sidewall **41** to enclose the upper end of the cyclone chamber **10**. In the illustrated example, the intersection or juncture **64** between the end wall **39** and the side wall **41** is a relatively sharp corner that does not include any type of angled or radiused surface. Similarly, in the illustrated embodiment, the lower end wall **40** meets the lower end of the cyclone sidewall **41** at a juncture **65** that is also configured as a relatively sharp corner.

Optionally, the juncture between the vortex finder **49** and the end wall **39** may be provided with an angled or curved surface. In the illustrated embodiment, the juncture **70** between the end wall **40** and the vortex finder **49** includes a curved surface **72** (FIG. **13**). The curved surface **72** has a radius **71**. The radius **71** may be selected based on the radius of the air inlet **42** (e.g. half of the diameter **48**), and optionally may be the selected so that the juncture surface **72** has the same radius as the air inlet **42**. Providing curved surface **72** at the juncture **70** may help reduce backpressure and may help improve cyclone efficiency.

Referring to FIG. **11**, in the illustrated embodiment the cyclone is a uniflow cyclone and an extension member **77** extends inwardly from a lower end wall of the cyclone chamber and may extend to a position that is proximate the lower end **105** of the screen **50** and may abut lower end **105**. The extension member **77** may be a closed member or, alternately, it may be a generally hollow tube-like member that extends between the lower end **105** of the screen **50** and the end wall **40** so as to provide a pre-motor filter dirt cup as discussed subsequently. Together, the vortex finder **49**, screen **50** and extension member **77** may form a generally continuous internal column member that extends between the first and second end walls **39** and **40** of the cyclone chamber **10**. Providing the projection member **77** may help direct air flow within the cyclone chamber, and may help support and/or stabilize the distal end **78** of the screen **50**.

Optionally, the juncture **79** between the end wall **40** and the projection member **77** may include a curved or angled juncture surface, similar to surface **72**, or may be provided as a sharp corner as illustrated.

In the illustrated embodiment the extension member **77** is integral with the screen **50** and vortex finder **49**, and remains within the cyclone chamber when the door **63** is opened. Alternatively, some or all of the extension member **77**, screen **50** and vortex finder **49** may be mounted to the end wall **40**, such that they move with the door **63** and is removed from the cyclone chamber when the door **63** is opened.

In the illustrated embodiment, the air inlet **42** is positioned at the juncture **65** between the sidewall **41** and the end wall **40** and is positioned such that the air inlet **42** is adjacent the sidewall **41** and the end wall **40** (i.e. there is no radial gap between the outer edge of the air inlet **42** and the sidewall

41 and no axial gap between the bottom of the air inlet **42** and the end wall **40**). Alternatively, the air inlet **42** may be spaced radially inwardly from the sidewall **41** or axially above the end wall **40**.

When combined with any other embodiment, the cyclone bin assembly **9** may be of any particular design and may use any number of cyclone chambers and dirt collection chambers. The following is a description of exemplified features of a cyclone bin assembly any of which may be used either individually or in any combination or sub-combination with any other feature disclosed herein.

Screen

The following is a description of a cyclone and a screen that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Optionally, a screen or other type of filter member may be provided on the cyclone air outlet **43** to help prevent fluff, lint and other debris from exiting via the air outlet. Referring to FIG. **11**, in the illustrated example a screen **50** is positioned at the air outlet **43** and connected to the vortex finder **49**. In FIG. **11** the screen is illustrated with a representation of its mesh in place, however for clarity the mesh has been omitted from the other Figures. The screen **50** is generally cylindrical in the illustrated embodiment, but may be of any suitable shape, including for example frusto-conical, in other embodiments. Optionally, the screen **50** can be removable from the vortex finder **49**.

Optionally, the screen **50** may be sized to have a cross-section area that is larger than, smaller than or generally equal to the air outlet **43** cross-sectional area. Referring to FIG. **13**, in the illustrated example, the diameter **52** of the screen **50** is less than the diameter **51** of the vortex finder **49** conduit providing the cyclone air outlet **43**. In this configuration, the radial surface **53** of the screen **50** is radially offset inwardly from the surface **54** of the vortex finder **49** by an offset distance **55**. Providing the offset gap **55** between the surfaces **53**, **54** of the screen **50** and vortex finder **49** may help provide a relatively calmer region (i.e. a region of reduced air flow turbulence and/or laminar air flow) within the cyclone chamber **10**. It may also assist the air that has been treated in the cyclone chamber to travel towards the vortex finder while mixing less with the air entering the cyclone chamber via the air inlet and thereby reduce the likelihood of dirt bypassing treatment in the cyclone chamber and travelling directly to the air outlet. Providing a relatively calmer air flow region adjacent the surface **53** of the screen **50** may help enable air to more easily flow through the screen **50** and into the vortex finder **49**, which may help reduce backpressure in the air flow path. Reducing back pressure may help improve the efficiency of the cyclone chamber and/or may help reduce power requirements for generating and/or maintaining a desired level of suction.

In the illustrated embodiment the screen **50** is of generally constant diameter. Alternatively, the diameter of the screen **50** may vary along its length. For example, the screen may be generally tapered and may narrow toward its upper end (i.e. the end that is spaced apart from the vortex finder **49**). The cross sectional area of the inner end of the screen may be 60-90% the cross sectional area of the air inlet and preferably is 70-80% the cross sectional area of the air inlet.

The screen may be tapered such that the width at the base of the screen (adjacent the vortex finder) is greater than the width at the upper end of the screen. In this configuration the cross-sectional area of the screen (in a plane that is generally perpendicular to the screen **50**) is greater at the base of the

15

screen than at its upper end. The amount of taper on the screen may be any suitable amount, and for example may be selected so that the cross-sectional area at the upper end of the screen is between about 60% and 90%, between about 70% and 80% and may be about 63%-67% of the cross-

Dirt Outlet

The following is a description of a cyclone dirt outlet that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Cyclone chamber **10** may be in communication with a dirt collection chamber by any suitable means. Preferably, as exemplified, the dirt collection chamber **11** is exterior to cyclone chamber **10**, and preferably has a sidewall **56** at least partially or completely laterally surrounds the cyclone chamber **10**. At least partially nesting the cyclone chamber **10** within the dirt collection chamber **11** may help reduce the overall size of the cyclone bin assembly. Referring to FIG. **2**, in the illustrated embodiment the cyclone chamber sidewall **41** is coincident with the sidewall **56** for approximately half its circumference. It will be appreciated that the dirt collection chamber may fully surround the cyclone chamber.

In the illustrated embodiment, the dirt outlet **44** is in communication with the cyclone chamber **10** and the dirt collection chamber **11**. Optionally, the dirt outlet **44** can be axially and/or angularly spaced from the cyclone air inlet. Preferably, the cyclone dirt outlet **44** is positioned toward the opposite end of the cyclone chamber **10** from the cyclone air inlet **42**. The cyclone dirt outlet **44** may be any type of opening and may be in communication with the dirt collection chamber to allow dirt and debris to exit the cyclone chamber **10** and enter the dirt collection chamber **11**.

In the illustrated example, the cyclone dirt outlet **44** is in the form of a slot bounded by the cyclone side wall **41** and the upper cyclone end wall **39**, and is located toward the upper end of the cyclone chamber **10**. Alternatively, in other embodiments, the dirt outlet may be of any other suitable configuration, and may be provided at another location in the cyclone chamber, including, for example as an annular gap between the sidewall and an end wall of the cyclone chamber or an arrestor plate or other suitable member. If the dirt outlet comprises an annular gap, then a cut out may be provided in the end of the sidewall of the cyclone chamber facing the end wall of the plate so that part of the sidewall may be further from the plate or end wall than the rest of the sidewall.

In a preferred embodiment, a cyclone chamber comprises a uniflow cyclone with a dirt outlet at the air outlet end. Preferably, the dirt outlet is a slot shaped dirt outlet and more preferably, the end wall abuts the sidewall of the cyclone chamber except at the location of the dirt outlet. In such a case, the air outlet or vortex finder preferably extends into the cyclone chamber further than the edge of the dirt outlet that is spaced furthest from the end wall.

Referring to FIG. **13**, the dirt slot **44** may be of any suitable length **57**, generally measured in the axial direction, and may be between about 0.1 inches and about 2 inches, or more. Optionally, the length **57** of the slot **44** may be constant along its width, or alternatively the length **57** may vary along the width of the slot **44**, preferably in the downstream direction as measured by the direction of air rotation in the cyclone chamber.

Optionally, the slot **44** may extend around the entire perimeter of the cyclone chamber (forming a generally continuous annular gap) or may extend around only a portion of the cyclone chamber perimeter. For example, the

16

slot may subtend an angle **73** (FIG. **10**) that is between about 5° and about 360°, and may be between about 5-150°, about 15-120°, about 35-75°, about 45 and about 90° and between about 60 and 80°. Similarly, the slot **44** may extend around about 10% to about 80% of the cyclone chamber perimeter, and preferably may extend around about 15% to about 40% of the cyclone chamber perimeter.

Optionally, the slot **44** may be positioned so that it is angularly aligned with the cyclone air inlet **42**, or so that an angle **60** (FIG. **10**) between the air inlet and the slot **44** (measured to a center line of the slot **44**) is between about 0 and about 350° or more, and may be between 5° and about 180° and may be between about 0 and about 90°. In some embodiments, the slot **44** can be positioned so that an upstream end of the slot (i.e. the end of the slot that is upstream relative to the direction of the air circulating within the cyclone chamber) is between about 0° and about 350° from the air inlet, and may be between about 5 and 180° and between about 0-90°, about 0-45° and about 0-15° downstream from the air inlet.

The dirt collection chamber **11** may be of any suitable configuration. Referring to FIG. **10**, in the illustrated example, the dirt collection chamber **11** includes a first end wall **61**, a second end wall **62** and the sidewall **56** extending therebetween.

To help facilitate emptying the dirt collection chamber **11**, one of or both of the end walls **61**, **62** may be openable. Similarly, one or both of the cyclone chamber end walls **39** and **40** may be openable to allow a user to empty debris from the cyclone chamber. In the illustrated example, the upper dirt chamber end wall **61** is integral with the upper cyclone end wall **39** and the lower dirt collection chamber end wall **62** is integral with, and openable with, the lower cyclone chamber end wall **40** and both form part of the openable bottom door **63**. The door **63** is moveable between a closed position (FIG. **11**) and an open position (FIG. **10**). When the door **63** is open, both the cyclone chamber **10** and the dirt collection chamber **11** can be emptied concurrently. Alternatively, the end walls of the dirt collection chamber **11** and the cyclone chamber **10** need not be integral with each other, and the dirt collection chamber **11** may be openable independently of the cyclone chamber **10**.

Pre-Motor Filter Housing

The following is a description of a pre-motor filter housing that may be used by itself in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Referring to FIG. **12**, in the illustrated embodiment, the cyclone bin assembly **9** includes a pre-motor filter chamber **31** that is positioned in the air flow path between the cyclone chamber **10** and the suction motor **8** (see also FIG. **11**). One or more filters can be provided in the pre-motor filter chamber **31** to filter the air exiting the cyclone bin assembly **9** before it reaches the motor **8**. Preferably, as exemplified, the pre-motor filter includes a foam filter **32** and a downstream felt layer **33** positioned within the pre-motor filter chamber **31**. Preferably, the filters **32**, **33** are removable (FIG. **12**) to allow a user to clean and/or replace them when they are dirty.

Referring to FIG. **12**, the pre-motor filter chamber **31** includes an upper end wall **110**, a sidewall **111** and a lower end wall **112**. Optionally, the sidewalls **111** of the pre-motor filter chamber **31** can be at least partially transparent so that a user can visually inspect the condition of the filters **32**, **33** to determine if they require cleaning or replacement without having to remove the cyclone bin assembly **9**.

The open headspace or header between the upper end wall 39 of the cyclone chamber 10 and the upstream side 123 of the filter 32 defines an upstream air plenum 124 (see FIG. 13). Providing the upstream plenum 124 allows air to flow across the upstream side 123 of the filter 32. The open headspace or header downstream of the filters 32, 33, between the downstream side 125 of filter 33 and the upper wall 110, provides a downstream air plenum 126. Providing a downstream plenum 126 allows air exiting the filters 32, 33 to flow radially across the downstream side 125 of filter 33 and toward the pre-motor filter chamber air outlet 135. In use, air exits the cyclone chamber 10 via the air outlet 43 and flows into upstream plenum 124, through filters 32, 33, into downstream plenum 126 and into the air outlet 135 of the pre-motor filter housing.

In the illustrated embodiment, the air outlet 135 is provided in the lid 36 and has an inlet end 136 in the pre-motor filter chamber (FIG. 12) and an outlet end 137 provided on the outer surface of the cyclone bin assembly (FIGS. 10 and 4). To provide air flow communication between the pre-motor filter chamber 31 and the suction motor 8, the outlet end 137 is configured to mate with the inlet end 138 of a motor air flow passage 139 provided in the surface cleaning unit 4. The motor air flow passage 139 is in air flow communication with the air inlet 113 of the suction motor 8.

Referring to FIG. 12, most of the upper end wall 110 and sidewall 111 may be provided by the inner surface of the lid 36, which may be opened to provide access to the filters 32, 33. In the illustrated embodiment, opening the lid 36 exposes the downstream side 125 of filter 33, which is generally the cleaner side of the pre-motor filter. Configuring the pre-motor filter chamber so that the clean, downstream side of the filter is exposed to the user when the lid 36 is opened allows a user to grasp the clean side 125 of the filter 33. This may allow the user to remove or manipulate the filter 33 while holding its clean side 125, and may eliminate the need for a user to grasp or otherwise contact the relatively dirtier, upstream side of the filter.

Optionally, filter 33 may be connected to filter 32 so that a user grasping the clean side 125 may be able to remove both filters 32, 33. Alternatively, the filter 33 may be removable independently from the filter 32. In such a configuration, removing the filter 33 will expose the downstream side 140 of the filter 32. While potentially not as clear as surface 125, the downstream side 140 of filter 32 is likely to be cleaner than upstream side 123. In this configuration, a user can grasp filter 32 via downstream side 140 and can avoid having to touch or otherwise contact the dirtier upstream side 123.

Optionally, some or all of the intersections between the vortex finder and wall 110, the walls 110 and 111, the walls 111 and 112, and the wall 112 and the pre-motor filter air outlet 135 may include angled or curved surfaces, for example like the surfaces within the cyclone chamber 10. Providing curved or smooth junctures within the pre-motor filter housing 31 may help improve air flow and may reduce backpressure in the air flow path. This may help improve the efficiency of the surface cleaning apparatus 1. Improving the efficiency may allow the surface cleaning apparatus to provide improved suction capabilities, and/or may allow the surface cleaning apparatus to maintain its existing suction capabilities while requiring a smaller, less powerful motor 8.

In the illustrated example, the bottom wall 112 includes a plurality of supporting ribs 130 that project upwards from the wall 112 into the chamber 31. The ribs 130 are configured to contact the upstream side 123 of the filters (in this example felt filter 32) in the chamber 31 and to hold it above

the wall 112, thereby help to maintaining the downstream plenum 126. The ribs 130 are spaced apart from each other to allow air to flow between them, within the plenum 126, and toward the suction motor air inlet 113. In the illustrated embodiment, the upper wall 110 also includes a plurality of ribs 130 for contacting the upstream side 125 of the filters (in this example filter 33) and to maintain a spacing between the upstream side 125 and the wall 110 to provide the upstream plenum 126.

Optionally, some or all of the support ribs in the pre-motor filter chamber 31 may be configured to help guide or direct the air flowing through the downstream plenum 126. For example, some of the ribs may be configured to help induce rotation of the air within the plenum 126, before it flows into the suction motor 8. Preferably, this pre-rotation of the air flow can be selected so that the air is rotated in the direction of revolution of the suction motor 8. Pre-rotating the air in this manner may help improve the efficiency of the surface cleaning unit 4. The ribs may be configured in any suitable manner to help impart rotation to the air flow.

The ribs 130 define a rib height 133. If the lower wall 112 of the pre-motor filter is flat, the height 133 of each rib 130, 131 may remain constant along its entire width. Alternatively, if the lower wall 112 varies in height, (e.g., the ribs extend to a trumpet shaped portion of a vortex finder, then the ribs 130, 131 may also vary in height so as to provide a planar support surface for the filter. Preferably, the ribs 130, 131 are configured such that the upper ends of the ribs 130, 131 lie in a common plane to support the filter 33, and the lower ends of the ribs are in contact with the wall 112.

Pre-Motor Filter Dirt Chamber and Filter Cleaning Member

The following is a description of a pre-motor filter dirt chamber and a filter cleaning member, each of which may be used separately or together in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

When the surface cleaning apparatus 1 is in use the upstream side 123 of the filter 32 may become soiled and/or partially blocked by dust and other relatively fine debris that is carried out of the cyclone chamber 10. If the upstream side 123 of the filter 32 becomes sufficiently blocked, air flow through filter 32 may be compromised and efficiency of the surface cleaning apparatus 1 may decrease. One method of cleaning the upstream side 123 of the filter 32 is for a user to remove the filter 32 as described above, clean the surface 123 and replace the filter 32 within the pre-motor filter chamber 31. Optionally, instead of cleaning the filter 32, a user may insert a new filter. Alternatively, instead of removing the filter 32 from the pre-motor filter chamber 31, the surface cleaning apparatus 1 may be configured to allow the filter 32, particularly the upstream side 123, to be cleaned in situ, without removing the filter 32 from the pre-motor filter chamber 31. Dirt and debris may be extracted from the upstream side 123 using any suitable mechanism, including, for example, banging to tapping one or more sides of the pre-motor filter chamber 31 and/or the pre-motor filter to dislodge the dirt and using a mechanical and/or electro-mechanical mechanism to help dislodge the debris. Examples of such mechanisms may include, for example, a scraper or other mechanical member that contacts and cleans the surface 123 and a shaker or beater type of mechanism that can shake the filter 32 to help dislodge the debris.

Alternately, or in addition, the pre-motor filter chamber 31 may be configured to receive fine dirt and debris from the upstream side 123 and direct the debris into a fine particle collection chamber or pre-motor filter dirt chamber that can collect the dislodged debris. The fine particle collection

chamber may be a portion of the primary dirt collection chamber **11**, or may be provided as a separate chamber. The fine particle collection chamber may be positioned directly below the upstream side of the pre-motor filter so that dirt falls downwardly into the chamber or it may be laterally spaced so that the dirt is conveyed laterally, e.g., by a ramp or an angled surface, to the chamber.

Referring to FIG. **13**, in the illustrated embodiment, the cyclone bin assembly **9** includes a pre-motor filter dirt chamber **140** for receiving debris **141** that is dislodged from the upstream upside **123** of filter **32**. In the illustrated embodiment, the dirt chamber **140** is located within the extension member **77**, which is inside the cyclone chamber **10**. In this configuration, there is no communication between the dirt chamber **140** and the dirt chamber **11**, nor do they share any walls or components in common. Alternatively, the dirt chamber **140** may be nested within the dirt chamber **11** and/or may have one or more surfaces or walls in common with the dirt chamber **11**.

In the illustrated example, the bottom wall **112** of the pre-motor filter chamber **31** (which is coincident with the upper wall **39** of the cyclone chamber **10** in this example) is curved downwardly toward the air inlet **43**. Curving the wall **112** in this manner may help guide the debris toward the air outlet **43**. When the air flow through the cyclone chamber **10** is off (i.e. when the cyclone bin assembly **9** is removed and/or when the surface cleaning apparatus is off), the debris **141** on wall **112** may fall downwardly though the vortex finder **39**, through the air outlet, pass through the interior of the screen **50** and fall into the dirt chamber **140**. Because the dirt chamber **140** is positioned below the air flow openings in the screen **50** it may be a relatively low air flow region when the surface cleaning apparatus is in use. This may allow debris **141** that has accumulated in dirt chamber **140** to remain in the dirt chamber **140** if the surface cleaning apparatus **1** is used prior to emptying the dirt chamber **140**, as the debris **141** in chamber **140** will tend not to be re-entrained in the air flowing into the screen **50** and upwardly though the air outlet **43**.

The dirt chamber **140** includes a sidewall **142** and a bottom wall **143**. The top of the chamber **140** is open to receive the debris **141**. Referring to FIG. **10**, in the illustrated embodiment the lower end of the dirt chamber **140** is integral with the floor **40** of the cyclone chamber and is part of the openable door **63**. In this configuration, the pre-motor filter dirt chamber **140** is contained within the cyclone bin assembly **9**, and is therefore removable from the surface cleaning unit **4** with the cyclone chamber **10**, dirt chamber **11** and pre-motor filter chamber **31** for emptying and/or cleaning. Preferably, as illustrated, the dirt chamber **140** can be removed in its closed configuration to help prevent dirt and debris from spilling when the cyclone bin assembly **9** is manipulated.

In this configuration, opening the door **63** simultaneously opens the cyclone chamber **10**, the dirt chamber **11** and the pre-motor filter dirt chamber **140**. Alternatively, the pre-motor filter chamber **140** can be configured so that it is openable in combination with only one of the cyclone chamber **10** and/or dirt collection chamber **11**, or independently from any other chamber.

For example, referring to FIG. **14** the cyclone bin assembly **9** can include a modified bottom door **63** that includes two separately openable portions **63a** and **63b** that are pivotally mounted about hinge **63c**. Each door portion **63a**, **63b** can be held closed by a corresponding, releasable latch **151a** and **151b** (similar to latch **151** that holds the door **63**

closed). In this configuration, the dirt chamber **11** can be emptied independently of the cyclone chamber **10** and dirt chamber **140**.

It will also be appreciated that the pre-motor filter chamber **140** may be removable in combination with only one of the cyclone chamber **10** and/or dirt collection chamber **11**, or independently from any other chamber.

Outwardly Biased Suction Hose

The following is a description of an outwardly biased suction hose and a suction hose chamber therefor, which may be used by itself or in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Referring to FIG. **1**, when a user is grasping the handle **17** to drive and maneuver the surface cleaning head **3**, the chassis portion **2** may be pulled along via hose **7**. Typically, a hose is extensible and is biased to a contracted position. If the portion of the hose **7** extending between the handle **17** and the chassis portion **2** is elastic or otherwise extensible it may be difficult for a user to accurately control the movement of the chassis portion **2**. For example, for a user to advance the chassis portion **2**, the hose **7** would have to be stretched to its maximum length before a suitable pulling force would be transmitted to the chassis portion **2**.

Alternatively, the hose may be configured as a compressible hose that is biased or sprung toward its extended configuration. The hose may include any type of suitable biasing member, such as a spring. The biasing member may be incorporated into the sidewall of the hose, or affixed to the interior or exterior surface of the hose. Accordingly, in its neutral state, the hose is extended and not contracted.

For storage and/or when the full length of the hose is not required for cleaning, the hose may be axially compressed into a retracted configuration (which may be at or close to its minimum length) within a suitable storage chamber, which may be part of a cord reel or part of a surface cleaning apparatus. The hose may be held in its compressed state within the storage chamber, which may help reduce the overall size of the surface cleaning apparatus. The hose may be held in place and compressed using any suitable securement mechanism.

When the surface cleaning apparatus is in use a desired length of hose may be metered out from the storage chamber by selectively releasing the securement mechanism and allowing the hose to spring or extend outward from the chamber due to its internal biasing member. When a desired length of hose is exposed, the user may re-engage the securement mechanism to contain the remainder of the hose within the storage chamber.

Preferably, the hose is not further extensible beyond its extended configuration. In this configuration, the exposed, uncompressed length of hose will not further stretch or extend when used to pull the chassis portion **2**.

Referring to FIG. **15**, another embodiment of a surface cleaning apparatus **1001** is shown. The surface cleaning apparatus **1001** is generally similar to apparatus **1**, and analogous features are identified using like reference characters indexed by **1000**.

In this embodiment, the hose **1007** is a compressible hose that can be compressed from an extended length to a compressed or retracted length. Referring also to FIG. **16**, the hose **1007** includes a biasing spring **1200** within the hose sidewall **1201** that is configured to bias the hose **1007** toward its extended length. The hose wall **1201** is preferably not otherwise extensible so that the hose **1007** generally cannot be stretched beyond its extended length. Optionally, in addition to a biasing spring **1200**, the sidewall **1201** may

also include one or more electrical conductors, e.g. wires **1203**, to transmit electrical power and/or control signals from the surface cleaning unit **4** to the handle **17**, and optionally downstream to the surface cleaning head **3** (for example to power a brush motor in the cleaning head **3**).

In the illustrated embodiment, a hose storage chamber **1204** is provided as a portion of the up flow conduit **16**, adjacent the handle **1017**. The hose storage chamber is configured to contain the compressed portions of the suction hose **1007**, and preferably has a length **1205** that is between about 50% and about 100% or more of the length of the hose **1007** in its fully compressed state, so that the chamber **1204** is sized to contain substantially all of the hose **1007** when it is compressed.

Referring also to FIG. 17, a schematic representation of the hose storage chamber **1204** illustrates a compressed portion **1207** of the hose **1007** contained within the storage chamber **1204**, upstream from the securement mechanism **1208** which holds the hose **1007** in its compressed state. An uncompressed or extended portion **1209** of the hose **1007** is located outboard or downstream from the securement mechanism **1208** and, in the example illustrated, extends through the hollow interior **1210** of handle **1017**.

In the illustrated embodiment, the securement mechanism **1208** includes a pair of latch members **1211** that are pivotally mounted within the chamber **1204** at pivot joints **1212**. Each latch member **1211** includes an engagement end **1213** that frictionally engages the outer surface of the hose **1007** to prevent relative axial movement between the engagement ends **1213** and the hose **1007**. When the latches **1211** are in their engaged position (FIG. 17), the uncompressed portion **1210** of the hose **1007** is maintained at a fixed length.

To allow additional hose **1007** to be drawn from the storage chamber **1204**, the latch members **1211** may be disengaged by a user. In the illustrated embodiment, each latch member **1211** includes a contact portion **1214** that can be engaged by the user. Squeezing or otherwise depressing the contact portions **1214** in the radial direction will cause the latch members **1211** to pivot about their respective pivot joints **1212** and will move the engagement ends **1213** out of contact with the outer surface of the hose **1007**. This will allow the compressed portion **1207** of the hose **1007** to expand under its own biasing force, and to expand until the latch members **1211** are re-engaged, or until the hose **1007** reaches maximum length.

Preferably, the latch members **1211** are biased toward their engaged positions, for example by springs **1215** so that the latch members **1211** hold the hose **1007** in place until triggered by the user.

Optionally, the open end of the storage chamber **1204** can include one or more guide members to help guide or direct the hose **1007** as it expands outwardly. This may help prevent kinks or other damage to the hose. In the illustrated embodiment, the storage chamber **1204** includes guide members in the form of rollers **1216** positioned toward the end of the chamber **1204**, and outside the latch members **1211**. The rollers **1216** may rollingly contact the hose **1007** as it expands and may help prevent the hose **1007** from being curved or bent too tightly or from otherwise becoming snagged to caught within the chamber **1204**.

Optionally, the rollers **1216** may be dampened or otherwise configured so that they provide a desired degree of rolling resistance when the hose **1007** is expanding. Providing resistance with the rollers **1216** may absorb some of the expansion force of the spring **1200**, and may help control the speed at which the hose **1007** expands from within the storage chamber **1204**. This may help prevent the hose **1007**

from expanding more than desired or from otherwise overwhelming the user when the latches **1211** are disengaged. While illustrated as standalone rollers **1216**, the rollers **1216** may be connected to any suitable drive apparatus (such as an electric motor) to further control the expansion of the hose **1007**.

When a user is finished with a given cleaning task, it may be desirable to re-compress the hose **1007** into the storage chamber **1204**. In the illustrated embodiment, the latches **1211** are configured as one-way latches so that when the hose **1007** is pushed inwardly (for example by the user) the latches **1211** will automatically pivot or ratchet to allow the hose **1007** to move freely inwardly (without needing to depress the contact portions **1214**), but will resist expansion of the hose **1007**. Alternatively, instead of manually inserting the hose **1007**, the hose storage chamber **1204** may include an automated hose compression system. For example, in the illustrated embodiment the rollers **1216** may be powered and may be operable to drive the hose **1007** into the storage chamber **1204**. Alternately, rollers **1216** may be electrically driven and used without latch members **1211** or the like.

Optionally, instead of being provided on the up flow duct, the hose storage chamber may be provided in the body of a surface cleaning apparatus, e.g., in a canister or base portion of the surface cleaning apparatus. Providing the hose storage chamber in the canister may position most of the weight of the hose within the canister (which rolls along the ground during normal use) and may therefore help reduce the amount of weight that is carried directly by the user holding the handle **17**. In the illustrated example such a hose storage chamber could be provided on the chassis portion **2** and/or the surface cleaning unit **4**.

Referring to FIG. 18, a schematic example of a canister style vacuum cleaner **2001** is shown. The surface cleaning apparatus **2001** is generally similar to the apparatus **1**, and analogous features are identified using like reference characters indexed by **2000**. In this embodiment, the surface cleaning unit **2004** is integral with the chassis portion **2002** to form the canister portion, and the hose storage chamber **2204** is provided within the canister portion.

Referring to FIG. 19, a schematic representation of an alternate embodiment of a hose storage chamber **3204** is shown. The hose storage chamber **3204** is generally similar to hose storage chamber **1204**, and analogous features are identified using like reference characters indexed by **2000**. In this embodiment, the securement mechanism **3208** includes rollers **3217** instead of latches. The rollers **3217** each include engagement projections **3218** for contacting and securing the hose **3007**. The rollers **3217** are preferably driven using any suitable driving mechanism (e.g. an electric motor and/or a spring that may be manually wound) and can be used to drive the hose **3007** into the storage chamber **3204** for storage. Optionally, the rollers **3217** need not be configured to drive the hose **3007** outward, and instead may simply be unlocked and allowed to rotate with the hose **3007** as it expands under its own biasing force. Preferably, the rollers **3217** can be locked in place in order to hold the hose **3007** in a fixed position.

Surface Cleaning Unit with Onboard Energy Storage Device

The following is a description of an portable surface cleaning unit with an on board energy storage member and alternate configurations of a base, which may be used by itself or in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Referring to FIG. 1, in the illustrated embodiment, the suction motor **8** is provided within the surface cleaning unit **8**. The electrical power cord **80** is, in this embodiment, connected to the surface cleaning unit **4** and remains connected when the surface cleaning unit **4** is separated from the chassis **2** (FIG. 5) to supply power to the surface cleaning unit **4**. In a first alternate embodiment, power cord **80** may be connected to the chassis portion **2** instead of directly to the surface cleaning unit **4**. In this first alternate configuration, the surface cleaning unit **4** may be electrically coupled to the chassis portion **2** when mounted on chassis portion **2**.

According to this embodiment, surface cleaning unit **4** includes at least one on board power supply or power storage device, which may comprise, for example, one or more of a battery, fuel cell and external combustion engine. In such configurations, the surface cleaning module may be powered by AC power when docked, and powered by the on board power storage device when detached from the chassis portion. The suction motor may be configured to run on AC power when the surface cleaning unit **4** is mounted on the chassis. If the on board power supply provides DC power (such as a battery) the suction motor may also be operable to run on DC power when the surface cleaning unit is detached (for example, the suction motor may have dual windings).

Optionally, the chassis portion or the surface cleaning unit **4** may include an electrical system for converting AC power to DC power (including, for example, a rectifier, inverter, transformer and other suitable equipment) so that the suction motor in the surface cleaning unit may run on DC power when detached and when docked. This may allow a single motor configuration to be used. Alternatively, the suction motor may be selected so that it is directly compatible with AC and DC power sources, such that a converter on the chassis portion to feed DC power to the surface cleaning unit is not needed.

Preferably, the on board power storage device in the surface cleaning unit can be recharged, and more preferably can be recharged when the surface cleaning unit is docked on the chassis portion. Optionally, the chassis portion can be configured to charge the surface cleaning unit while the suction motor is running (while the apparatus is in use), and/or while the suction motor is off (the apparatus is in storage).

In a second alternate embodiment, a different power cord **80** may be connected to the chassis portion **2** in addition to the power cord connected to the cleaning unit **4**. In a third alternate embodiment, power cord **80** may be selectively connectable to the chassis portion **2** and the surface cleaning unit **4**. In this third alternate configuration, the surface cleaning unit **4** may be electrically coupled to the chassis portion **2** when mounted on chassis portion **2** and power cord **80** is connected to chassis **2** or power cord **80** may be directly connected to the surface cleaning unit **4** and directly power the surface cleaning unit **4**.

Referring to FIG. 20, another embodiment of a surface cleaning apparatus **4001** and surface cleaning unit **4004** are shown. The surface cleaning unit **4004** is shown with its upper cover cut-away and cyclone bin assembly removed. The surface cleaning unit **4001** is generally similar to surface cleaning unit **1**, and analogous features are illustrated using like reference characters indexed by **4000**.

Referring to FIG. 21, in this embodiment, the electrical power cord **4008** is connected to the chassis portion **4002**, instead of the surface cleaning unit **4004**. To provide electrical communication, the chassis portion **4002** includes an electrical connector **4300** (preferably a female socket as

exemplified) and the surface cleaning unit **4004** includes a mating electrical connector **4301** (e.g., male prongs in the illustrated example) that is mated with the connector **4300** when the surface cleaning unit **4004** is docked on the chassis portion **4002**.

To power the surface cleaning unit **4004** when it is detached, in this embodiment the surface cleaning unit **4004** includes an on board power storage device in the form of batteries **4302** (FIG. 20), which are electrically connected to suction motor **4008**. When the surface cleaning unit **4004** is detached from its chassis portion **4002** the suction motor **4008** is powered by the batteries **4302**.

In the illustrated example, the suction motor **4008** is a DC motor, and the surface cleaning unit includes an on board converter module **4303** for converting AC power from the cord **4080** into DC power suitable for the motor **4008**. Preferably, the batteries **4302** can be rechargeable batteries, and when the surface cleaning unit **4004** is docked, AC power from the wall may be used to charge the batteries **4302**. The converter module **4303** is also configured to allow the batteries **4302** to be charged when the surface cleaning unit **4004** is connected to AC power. The converter module **4303** may include any suitable combination of components, including, for example, an inverter, a transformer and a rectifier.

Alternate Power Modes

The following is a description of a portable surface cleaning unit with alternate power modes, which may be used by itself or in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Referring to FIG. 22, a schematic representation of the surface cleaning apparatus **4001** is shown. Optionally, a controller **4450** can be provided to alter the operation of the suction motor **4008** based on its power supply. For example, when the controller senses that the surface cleaning unit **4008** is being powered by an external power supply (e.g., AC power via cord **4080**) the suction motor **4008** can be operated at a relatively high power or "full power" mode. Alternatively, when the surface cleaning unit **4004** is being powered by the on board power storage member (e.g. batteries and is being run on DC current), the controller may operate the motor **4008** at a relatively lower power level. Operating at a lower power level may help prolong the amount of cleaning time that can be obtained using the on board batteries.

FIGS. 23 and 24 illustrate example embodiments of a converter module **4303**. Generally, converter module **4303** operates to convert AC signals to DC signals. The converter module **4303** may also transform an input power signal to a signal suitable for the operation of the surface cleaning apparatus **4001**. It will be understood that converter module **4303** may be provided in one or more different configurations.

In FIG. 23, converter module **4303A** includes an input terminal **4309**, a rectifier block **4310**, a transformer block **4311** and output terminals **4312**, **4313**. The input terminal **4309** receives an input AC signal **4314** from the mating electrical connector **4301** and provides the input AC signal **4314** to the rectifier block **4310** and the transformer block **4311**. The rectifier block **4310** may include one or more electrical components for converting the input AC signal **4314** to a rectified signal **4315**. For example, the rectifier block **4310** can include one or more diodes in various configurations as known in the art. The rectifier block **4310** provides the rectified signal **4315** to the transformer block **4311**.

In some embodiments, the rectifier block **4310** can also include a filter or a regulator for stabilizing a version of the rectified signal **4315** prior to generating and providing the rectified signal **4315** to the transformer block **4311**.

The transformer block **4311** may include one or more electrical components for varying the rectified signal **4315** to a signal suitable for the operation of the surface cleaning apparatus **4001**. For example, the input power signal **4314** received at the input terminal **4309** may be from the wall outlet and therefore, the value of the input power signal **4314** may need to be lowered. As illustrated in FIG. **23**, the transformer block **4311** is coupled to the two output terminals **4312**, **4313**. The transformer block **4311** generates an output DC signal **4317** and an output AC signal **4318**, and then provides the output DC signal **4317** to the output terminal **4312** and the output AC signal **4318** to the output terminal **4313**.

As described above, the motor **4008** may be a motor that operates on AC power or DC power. When the motor **4008** operates on AC power, the motor **4008** can receive power via the output terminal **4313**. Alternatively, when the motor **4008** operates on DC power, the motor **4008** can receive power via the output terminal **4312**. The batteries **4302** may also be charged via the output terminal **4312**. For example, the batteries **4302** may be charged via the output terminal **4312** while the surface cleaning apparatus **4001** is docked on the surface cleaning unit **4**. The batteries **4302** may be charged while the surface cleaning apparatus **4001** is in use or when the surface cleaning apparatus **4001** is not in use.

In some embodiments, the converter module **4303** can include only one output terminal, such as the output terminal **4312**. Transformer block **4311** can therefore generate and provide only one output signal, such as the output DC signal **4317**, to the output terminal **4312**.

FIG. **24** illustrates a converter module **4303B**. The transformer block **4311** may be provided as two separate transformer blocks **4311A**, **4311B**. Similar to the transformer block **4311** of FIG. **24**, the transformer block **4311A** receives the rectified signal **4315** from the rectifier block **4310**. However, unlike the transformer block **4311** of FIG. **24**, the transformer block **4311A** generates only the output DC signal **4317**, which is then provided to the output terminal **4312**. The transformer block **4311B** receives the input AC signal **4314** from the input terminal **4309** in order to generate the output AC signal **4318**.

It will be understood that the rectifier block **4310** and the transformer block **4311** may be provided in a different order than as illustrated in converter modules **4303A**, **4303B**. For example, the transformer block **4311** may receive the input AC signal **4314** to generate a transformed signal which is either provided to the rectifier block **4310** for processing and/or directly to the output terminal **4313**.

Electrical Cord Reel

The following is a description of an electrical cord reel, which may be used by itself or in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

When the surface cleaning apparatus is not in use, it may be desirable to wind the electrical cord for storage. Optionally, a cord reel can be provided to wind and hold the cord **80**. The cord reel may be of any suitable configuration and may be a manually actuated reel (for example via a hand crank) or an automated reel. If the reel is automated (i.e. can wind the cord without manual user intervention), it may be driven by any suitable mechanism including, for example, a spring, a biasing mechanism and/or a motor. The motor used may be an electric motor that can be operated at a speed that

is suitable for winding the cord. If the motor is electric, preferably the cord reel is provided with a power source (either on board or as part of the surface cleaning apparatus) so that the cord reel motor can be powered even after the electrical cord has been unplugged.

Optionally, the cord reel, and associated power sources, controllers, switches, etc. can be internal (i.e. inside one portion of the surface cleaning apparatus) or external to the surface cleaning apparatus. For example, referring to FIG. **25**, if the electrical cord **80** is connected to the surface cleaning unit **4**, any suitable cord reel (illustrated schematically as box **400**) may be provided inside the surface cleaning unit **4**. Alternatively, referring to FIG. **26a**, if the electrical cord **4080** is attached to the chassis portion **4002**, a cord reel **4400** can be provided in the chassis portion **4002**.

In one embodiment, cord reel **4400**, may be configured to automatically wind or unwind the cord based on at least one operating condition of the surface cleaning apparatus. For example, the surface cleaning apparatus may include a controller **4450** that is capable of sensing or detecting an operating condition of the surface cleaning apparatus **4001** and then control the cord reel based on the operating condition. Such a cord reel may optionally, but need not, include any of the other features of a cord reel disclosed herein

For example, referring to FIG. **26b**, a schematic representation of a cord reel **4400** and a control system therefor is illustrated. While a schematic is illustrated, the control system may be of any suitable configuration. In the illustrated embodiment, the control system includes the controller **4450** (e.g. a PLC, microprocessor or onboard computer) that is communicably linked to the cord reel module **4400**. In this configuration, the cord reel **4400** includes a motor **4424** to drive the reel **4401** and an on board power supply in the form of batteries **4423** to power the motor **4424**. The controller **4450** is connected to control the operation of the motor **4424**.

One or more suitable sensors can be provided on the surface cleaning apparatus and connected to the controller **4450**. In the illustrated example, the control system includes a position sensor **4451** connected to the controller. The position sensor **4451** can be any suitable type of sensor that can detect the rate and direction of movement of the chassis portion **4002**. For example, the sensor **4451** can be an encoder that can measure the speed and direction of rotation of the wheels **100**, or may be an optical sensor that can determine movement by visually tracking the surface under the chassis portion **2** or the rotation of a wheel of the chassis, or any other suitable sensor. In one embodiment, the controller can be configured to determine when the vacuum cleaner is moving forward and to unwind cord **80** from the reel **4401** at a given rate based on the speed of the movement. Alternately or in addition, the controller may be configured to wind cord **80** onto the reel **4401** when the chassis portion **4002** is moved backward. Alternatively, the sensor **4451** may be a receiver (e.g. a radio receiver) configured to receive external data, for example from a transmitter positioned adjacent the wall. Using this signal, the controller may be able to determine the position of the chassis portion **4002** relative to the transmitter and to unwind cord as the chassis portion **4002** moves farther from the transmitter and to wind the cord **80** as the chassis portion **4002** moves closer to the transmitter. Such a system may also be used in combination with a cord reel **400** that is provided in the carryable surface cleaning unit **4**, which may not have wheels or be in visual proximity to the ground.

An analogous control system, and or controller, may be included in other portions of the surface cleaning apparatus, including, for example, in the surface cleaning unit **4** or **4004**, and optionally in the body or control/drive module of an external cord reel.

In another embodiment, the cord reel may be a separate unit (i.e., it may not be incorporated into the surface cleaning unit **4** or chassis) and may have an on board energy storage member (e.g., one or more batteries). Preferably, the batteries are charged when the cord reel is plugged into the wall. The cord reel may have a first short cord that is configured to plug into a household electrical outlet and a second longer cord that is configured to be plugged into the surface cleaning apparatus. Such a cord reel may optionally, but need not, include any of the other features of a cord reel disclosed herein.

For example, referring to FIG. **26c**, the cord reel **4400** may be separable from the chassis portion **4002** and may be configured as an external cord reel. In this configuration, the cord reel **4400** may be separated from the chassis portion **4002** and rested on the ground, for example adjacent a power socket. The cord **4080** can then be unwound from the reel **4400** as required to allow the chassis portion **4002** to be moved away from the wall socket. This may reduce the weight of the chassis portion **4002**. In this embodiment, the controller **4450** may be located within the external cord reel, instead of within the surface cleaning unit **4004** or chassis portion **4002**. Optionally, the sensor **4451** can be a radio receiver and the chassis portion **4002** can include a corresponding transmitter **4452** to allow the controller **4450** to determine the distance of the chassis portion **4002** from the cord reel **4400**, and to unwind and/or wind cord **80** as required.

Referring to FIG. **26d**, an analogous system can be used if an external cord reel module **400** is connected to the surface cleaning unit **400**, instead of the chassis portion **2**.

In the illustrated example, the cord reel **400** may be a spring-powered cord reel that can wind the cord using potential energy stored in a spring. To activate the cord reel, a user can press the cord reel button **81** on the surface cleaning unit **4** to retract the cord **80**. Alternatively, if the cord reel **400** were electrically driven, batteries could be provided within the surface cleaning unit **4** (for example, similar to the batteries **4302**) to power the cord reel.

In another embodiment, the cord reel may be configured as a dual-wind cord reel, in which the reel is positioned between the ends of the cord and winds the cord in two directions simultaneously (e.g. one revolution of the reel winds two lengths of cord). Such a cord reel may optionally, but need not, include any of the other features of a cord reel disclosed herein.

Optionally, the dual-wind cord reel may be configured so that it connects to the cord without interrupting or forming part of the electrical connection between the ends of the cord. In this configuration, the cord reel need not include any type of rotatable or pivotal electrical connections, or any electrical connections at all, and may be referred to as a sealed or brushless cord reel. In this configuration, the integrity of the electrical insulation of the cord remains intact, which may be desirable if used in wet or other hazardous locations.

Referring to FIG. **27**, an embodiment of a cord reel **401** that is suitable for use with surface cleaning apparatus **1**, **4001** and/or other surface cleaning apparatuses is shown. The cord reel **401** includes a body **402** that rotatably supports a reel member **403**. The reel includes an inner sidewall **403** that is rotatable about a reel axis **404**. A central

spindle member **405** projects axially from the reel member **403** and rotates with the inner sidewall **403**. A handle **406** is provided toward the top of the body **402** to allow a user to grasp and/or carry the cord reel **401** when it is separated from the surface cleaning apparatus.

In the illustrated embodiment, the cord reel **401** is configured to be attached to a portion of the cord **80** that is intermediate its two ends and preferably proximate the center of the power cord and, more preferably, the reel **401** is connected to the middle of the cord **80**. Connecting to the middle of the cord **80** may help ensure that the cord **80** winds generally evenly around the spindle **405**. Optionally, to help retain the cord on the spindle **405** the reel **401** can include an outer sidewall **407** that is connected to the free end **408** of the spindle **405**. In the illustrated embodiment the outer sidewall **407** is detachable from the spindle **405**. This may allow the cord **80** to be connected to the cord reel **401** and may help facilitate removal of the wound cord from the reel.

For example, in the illustrated embodiment, to attach the cord reel **401** to the cord **80**, the cord **80** is axially inserted into a slot **410** on the spindle **405**. The slot **410** can be sized to receive a given cord **80**, and may extend along some, or substantially all of the length of the spindle **405**. Extending the slot **410** the entire length **411** of the spindle **405** may allow the cord **80** to be positioned at any location along the spindle length. Inserting the cord **80** axially into the slot **410** eliminates the need to feed either end of the cord **80** through the slot **410** (or other portions of the reel **401**), which may allow for the slot **410** to be sized to have a width **412** that is generally equal to the width **413** of the cord **80**.

Optionally, to help position the cord reel **401** in the middle of the length of the cord **80**, the cord **80** may be provided with a locating member identify the middle of the cord. Preferably, the locating member is compatible with the cord reel **401** and more preferably, can fit within or otherwise engage the spindle **405** (or other suitable portion of the cord reel **401**).

Referring to FIG. **27a**, one example of a locating member is stripe **413** provided on cord **80**. The stripe **413** is visual indication of the middle of the cord **80**, and a user may align the cord reel **401** with the cord **80** by inserting the striped portion **413** into the slot **405**. Optionally, the stripe **413** may be integral with the cord **80** (e.g. formed as a differently colored portion of the cord **80** insulation, etc.) or may be painted or otherwise marked on the outer surface of the cord **80**. While a stripe is illustrated, the visual indicator may be any suitable feature, including, for example, a sticker or wrapper, lettering or other words, a change in texture of the cord **80** surface, etc.

Optionally, instead of a visual indicator, the locating member may be a physical object that is configured to engage or mate with the spindle **405**. For example, referring to FIGS. **28a-c**, instead of (or in addition to) a visual stripe **413**, a locating member may be provided as an anchor member **413a**. In the illustrated example the anchor member **413a** is a generally triangular member that is attached to the cord **80**. The anchor member **413a** includes two mating halves **416** and **417** each of which includes a cord channel **418** extending therethrough. The halves **416**, **417** can be fastened together using any suitable mechanism, including fasteners inserted into apertures **419**, a snap fit or press fit and other connecting clamps or clips. Optionally, the anchor member **413a** can be provided separately from the cord **80**. This may allow a user to attach the anchor member **413a** to any cord the user wishes to use in combination with the cord reel **401**.

In the illustrated embodiment, in addition to the cord slot 410, the spindle 405 includes a central bore 418 that is configured to slidably receive the anchor member 413a. To accommodate the triangular anchor member 413a, the bore 418 has three sides 119a-c. In other configurations, both the anchor member 413a and bore 418 may have a different, corresponding shape, including, for example, square, pentagon, hexagon, etc. Referring to FIG. 33, the anchor member 413a is shown inserted into bore 418. In this configuration, the anchor member 413a can also act as an alignment or keying member as it is configured to fit into the bore 418 in an orientation such that the cord 80 also passes through slots 410.

In some configurations, when the spindle 405 is rotated faces 119a-c may engage and exert forces on corresponding faces on the anchor member 413a. This may help reduce the amount of force exerted directly on the cord 80 by the reel 401, which may help reduce cord damage.

Referring to FIG. 27b, when the locating member (of any suitable configuration) is nested within the spindle 405, the outer sidewall 407 can be attached (for example snapped in place or attached using clips or other suitable means) to secure the cord 80 on the reel 401. The spindle 405 and sidewalls 403 and 407 can then be rotated using any suitable means to wind the cord 80 onto the reel 401. In the illustrated embodiment, both sides of the cord are drawn inwardly toward the reel 401 and wrapped around the spindle 405.

Referring to FIG. 27c, when the cord 80 is fully wound on the reel 401, both ends of the cord 80, female socket 414 and male prongs 415, can be pulled within the perimeter of the cord reel 401. In this embodiment, the prongs 415 are configured to connect to a standard wall socket, and the socket 414 is configured to detachably connect to a corresponding port/coupling on the surface cleaning apparatus. Alternatively, the female end of the cord 80 may be fixedly connected to the surface cleaning apparatus, and need not be detachable.

Referring to FIG. 27d, to remove the cord 80 from the reel 401, the user may unwind the reel or alternatively may remove outer sidewall 407 and then axially slide the coiled cord 80 off of the spindle 405. This may allow a user to quickly remove the entire cord 80 from the reel 401 without having to unwind its entire length.

The cord reel 401 may be driven (i.e. wound and/or unwound) using any suitable mechanism, including for example a manual crank and a powered motor. Optionally, the reel 401 may include more than one driving mechanism, which may allow the reel to be operated under a variety of conditions.

Referring to FIG. 27b, in the illustrated embodiment the cord reel 401 includes a drive module 420 provided at the lower end of the body 402. In this configuration, the drive module 420 is generally opposite the handle 406 and is positioned below the spindle 405. Preferably, the bottom surface 421 of the drive module 420 cooperates with the lower surface 422 of the rest of the body 402 to provide a base for the cord reel 401. More preferably, the base is configured to support the cord reel in a generally upright position if/when it is placed on a flat surface (such as the ground). This may allow the cord reel 401 to remain upright when detached from the surface cleaning apparatus and positioned on the ground.

The drive module 420 preferably includes an onboard energy storage member in the form of batteries 423 and an electric drive motor 424. The drive motor 424 can be connected to the spindle 405 in any suitable manner in order

to drivingly rotate the spindle 405. In the illustrated embodiment, the perimeter of the inner sidewall 403 is provided with a plurality of gear teeth 425 which extend into the drive module 420. Inside the drive module 420, the motor 424 is connected to a driving pinion or gear with teeth that mesh with the teeth on the sidewall 425.

A switch 425 is wired between the batteries 423 and the motor 424 to control the operation of the motor 424, and the subsequent rotation of the spindle 405. The switch 425 may be any suitable type of switch, and in the example illustrated is a three-position switch. In this configuration, the switch can be moved into a "wind" position in which it causes the motor 424 and spindle 405 to rotate in one direction, an "unwind position" in which it causes the motor 424 and spindle 405 to rotate in the opposite direction, and an off position in which the motor 424 does not rotate. This may allow for powered winding and unwinding of the cord. Alternatively, or in addition, the drive mechanism may include a clutch or other suitable device so that in addition to being unwound using motor 424, the cord may be unwound simply by pulling on one or both of its ends, and the spindle 405 is allowed to rotate in response to such tension on the cord 80.

In addition to winding and unwinding, the motor 424 may be equipped with a torque sensor (e.g. current monitoring sensor) or other type of controller that can disengage or deactivate the motor 424 if the tension on the cord 80 exceeds a predetermined threshold (e.g. if the cord 80 is stuck or the 401 reel is jammed). This may help prevent damage to the motor 424, the cord 80 and the reel 401.

Preferably, if batteries are provided on board the cord reel, they are preferably rechargeable. The batteries may be charged if the cord reel 401 is connected to the body of the surface cleaning apparatus which has an on board energy storage member, and/or by placing the drive module 420 on an independent charging station or by connecting it to an external power source (e.g. a wall socket). Optionally, referring to FIG. 29, the drive module 420 may be removable from the body 402. Removing the drive module 420 may help reduce the overall size and weight of the cord reel 401. It may also allow the drive module 420 (if it includes the batteries) to be charged separately from the cord reel 401, and/or to be serviced or replaced with a different drive module 420.

Referring to FIG. 30, as an alternative to the electric drive module 420 or as a supplement thereto, the cord reel 401 may also include a manual drive mechanism to wind the cord 80. This may be useful if the drive module 420 is removed and/or if the batteries 423 are dead. In the illustrated embodiment, the manual drive mechanism is provided in the form of a hand crank 425. The hand crank 425 includes a hand grip portion 426 and a linkage arm 427. The outer end 428 of the linkage arm is connected to the hand grip 426 and the inner end 429 is connected to the inner sidewall 403 and spindle 405. Rotating the hand crank 425 winds and unwinds the cord 80. When not in use, the hand grip portion 426 can be moved from a deployed position (FIG. 30) to a retracted position (FIG. 31), which may help reduce the overall size of the cord reel 401. Reducing the size of the cord reel 401 may help facilitate storing and/or mounting the cord reel 401 on a surface cleaning apparatus.

As exemplified in FIG. 32, the cord reel 401 may be configured to be mounted to, and carried on, the surface cleaning apparatus 1. To accommodate the external cord reel 401, the surface cleaning unit 4 may include a reel mount 430 and the cord reel 401 may include a complimentary mounting flange 431 provided on the back of the body 402

(FIG. 30). The mounting flange **431** may be configured to fit within the cord mount **430** and can be held in place by gravity, and/or the use of any suitable securing or locking members, including, latches, magnets, pins, detents, clips and other fasteners.

Preferably, in addition to providing a physical connection, the cord mount **430** and flange **431** can also include reciprocal electrical connectors (e.g. a mating socket and prongs). In this configuration, when the cord reel **401** is docked on the surface cleaning unit **4**, and the surface cleaning unit **4** is powered (either by an external source or an on board source) the cord reel **401** can receive power from the surface cleaning unit **4**, or vice versa. This may allow the batteries **423** to be charged when the cord reel **401** is mounted on the surface cleaning apparatus **1**. Alternately, the reciprocal electrical connectors may be used to power the surface cleaning unit when the power cord is plugged into an electrical outlet.

Optionally, the cord reel **401** may carry the only cord **80** provided with the surface cleaning apparatus **1**. In such a configuration, one end of the cord **80** is connectable to a port or connector on the surface cleaning apparatus **1**. Alternatively, the cord reel **401** may carry an additional or supplemental cord **80**, and the surface cleaning apparatus **1** may include at least one internal cord reel as well. In such a configuration, the cord **80** on the cord reel **401** may function as an extension cord, and one end of the cord may be connected to the wall socket while the other end of the cord is coupled to the free end of the electrical cord that is integral the surface cleaning apparatus.

In the illustrated embodiment, mounting the cord reel **401** onto the back side of the surface cleaning unit **4** could potentially interfere with the air flow exiting the clean air outlet **6**. To help facilitate air flow, the inner sidewall **403** and outer sidewall **407** are provided with a plurality of air flow apertures **432** to allow air to flow through the cord reel **401**.

In an alternate embodiment, the cord reel could produce a DC output, such as by having an on board power supply.

Any of the features of the cord reels disclosed herein may be used with any other type of surface cleaning apparatus. The following description exemplifies a number of the features of a cord reel disclosed herein in an upright-style surface cleaning apparatus. Referring to FIG. 34, another embodiment of an upright-style surface cleaning apparatus **5001** is shown. Surface cleaning apparatus **5001** is generally similar to surface cleaning apparatus **1**, and analogous features are identified using like reference characters indexed by **5000**.

In this embodiment, the chassis portion **5002** is configured as the upper portion of the surface cleaning apparatus, and includes the rigid up flow duct **5016**. In FIG. 34, the surface cleaning unit **5004** is illustrated including an optional internal cord reel **5400** that may include any of the features of the cord reels described herein. Referring to FIG. 35, the surface cleaning apparatus **5001** is illustrated with an external cord reel **5400** that includes a motor **5424**, batteries **5423**, controller **5450**, sensor **5451** and transmitter **5452** as described herein. Optionally, some or all of these features may also be provided in the internal cord reel **5400** in FIG. 34. Preferably, the surface cleaning unit **5004** is detachable from the chassis portion **5002**, which may allow the user to reconfigure the surface cleaning apparatus **5001** into a variety floor and above-floor cleaning modes.

Hand Carriable Surface Cleaning Apparatus

The following description exemplifies a number of the features disclosed herein in a hand carryable surface clean-

ing apparatus (e.g., a hand vacuum cleaner, a pod vacuum cleaner or any other surface cleaning apparatus that may be carried by a handle or a shoulder strap or the like). Referring to FIG. 37, another embodiment of a hand carryable surface cleaning apparatus **10900** is shown.

The surface cleaning apparatus **10900** includes a main body **10901** having a handle **10902**, a dirty air inlet **10903**, a clean air outlet **10904** (see for example FIG. 26) and an air flow path extending therebetween. In the embodiment shown, the dirty air inlet **10903** is the inlet end of connector **10906**. Optionally, the inlet end **10905** can be used to directly clean a surface. Alternatively, the inlet end can be connected to the downstream end of any suitable cleaning tool or accessory, including, for example a wand, a nozzle and a flexible suction hose.

The connector **10906** may be any suitable connector that is operable to connect to, and preferably detachably connect to, a cleaning tool or other accessory. Optionally, in addition to provide an air flow connection, the connector may also include an electrical connection **10909** (FIG. 38). Providing an electrical connection **10909** may allow cleaning tools and accessories that are coupled to the connector **10906** to be powered by the surface cleaning apparatus **10900**. For example, the surface cleaning unit **10900** can be used to provide both power and suction to a surface cleaning head, or other suitable tool. In the illustrated embodiment, the connector **10909** includes an electrical coupling in the form of a female socket member, and a corresponding male prong member may be provided on the cleaning tools and/or accessories. Providing the female socket on the electrified side of the electrical coupling may help prevent a user from inadvertently contacting the electrical contacts.

Referring to FIG. 39, a construction technique that may be used by itself or with any other feature disclosed herein is exemplified. In this embodiment, the main body portion **10901** of the surface cleaning apparatus includes a core cleaning unit **11000** and an outer shell **11001**. In the illustrated example, the core cleaning unit **11000** is a generally, self-contained functional unit that includes the dirty air inlet **10903**, air treatment member **10910**, pre-motor filter chamber **10956**, suction motor **10911** and clean air outlet **10904**. The outer shell includes mating side panels **11002**, the handle portion **11003** of the surface cleaning apparatus (including the primary power switch **10985**) and an openable pre-motor filter chamber cover **10959**. When the outer shell **11001** is assembled around the core cleaning unit **11000** the exposed outer surfaces of the surface cleaning apparatus **10900** are formed from a combination of portions of the core cleaning unit **11000** and the outer shell **11001**. For example, the external suction motor housing **10912** and handle **10902** are provided by the outer shell **11001**, whereas the shell is shaped so that portions of the cyclone bin assembly **10910** sidewalls remain visible in the assembled configuration. If these portions are at least partially transparent, they can allow a user to see into the dirt collection chamber **10914** to determine if the dirt collection chamber **10914** is getting full.

From the dirty air inlet **10903**, the air flow path extends through the cyclone bin assembly **10910** which forms part of the main body of the surface cleaning apparatus. A suction motor **10911** (see FIG. 44) is mounted within a motor housing frame **11004** (FIG. 39) of the core cleaning unit **11000** and is in fluid communication with the cyclone bin assembly **10910**. In this configuration, the suction motor **10911** is downstream from the cyclone bin assembly **10910** and the clean air outlet **10904** is downstream from the suction motor **10911**.

Referring to FIGS. 41 and 44, a uniflow cyclone and/or a cyclone with rounded junctures, and/or a cyclone with an insert member any of which may be used by itself or with any other feature disclosed herein is exemplified. In the illustrated embodiment, the cyclone bin assembly 10910 includes a cyclone chamber 10913 and a dirt collection chamber 10914. The dirt collection chamber 10914 comprises a sidewall 10915, a first end wall 10916 and an opposing second end wall 10917. The dirt collection chamber 10914 may be emptyable by any means known in the art and is preferably openable concurrently with the cyclone chamber 10913. Preferably, the second dirt collection chamber end wall 10917 is pivotally connected to the dirt collection chamber sidewall by hinge 10919. The second dirt collection chamber end wall 10917 functions as an openable door to empty the dirt collection chamber 10914 and can be opened (FIGS. 42 and 43) to empty dirt and debris from the interior of the dirt collection chamber 10914. The second dirt collection chamber end wall 10917 can be retained in the closed position by any means known in the art, such as by a releasable latch 10919a. In the illustrated example, the hinge 10919 is provided on a back edge of the end wall 10917 and the latch 10919a is provided at the front of the end wall 10917 so that the door swings backwardly when opened. Alternatively, the hinge 10919 and latch 10919a may be in different positions, and the door 10917 may open in a different direction or manner. Optionally, instead of being openable, the end wall 10917 may be removable.

In the embodiment shown, the cyclone chamber 10913 extends along a cyclone axis 10920 and is bounded by a sidewall 10921. The cyclone chamber 10913 includes an air inlet 10922 and an air outlet 10923 that is in fluid connection downstream from the air inlet 10922 and one dirt outlet 10924 in communication with the dirt collection chamber 10914. In this embodiment, the dirt collection chamber 10914 is positioned adjacent the cyclone chamber 10913 and at least partially surrounds the cyclone chamber 10913 in a side-by-side configuration.

Preferably, the air inlet 10922 is generally tangentially oriented relative to the sidewall 10921, so that air entering the cyclone chamber will tend to swirl and circulate within the cyclone chamber 10913, thereby dis-entraining dirt and debris from the air flow, before leaving the chamber via the air outlet 10923. The air inlet 10922 extends along an inlet axis 10925 that is generally perpendicular to the cyclone axis 10920, and in the illustrated example is generally parallel to and offset above the suction motor axis 10926.

In the illustrated example, the cyclone air outlet 10923 includes a vortex finder 10927. Optionally, a screen 10928 can be positioned over the vortex finder 10927 to help filter lint, fluff and other fine debris. Preferably, the screen 10928 can be removable.

The air inlet 10922 has an inlet diameter 10934, and a related inlet flow cross-sectional area (measure in a plane perpendicular to the inlet axis). Preferably, the air outlet 10923 is sized so that the diameter 10932 of the air outlet 10923, and therefore the corresponding flow area of the air outlet 10923, is the same as the diameter of the air inlet. Alternatively, the air outlet diameter 10932 may be between about 50% and about 150%, and between about 85-115% of the air inlet diameter 10925.

In the example illustrated the cyclone bin assembly 10910, and the cyclone chamber 10913 are arranged in a generally vertical, uniflow cyclone configuration. In a uniflow cyclone, the air inlet is located toward one end of the cyclone chamber and the air outlet is provided toward the other end of the cyclone chamber. In this configuration, air

enters one end of the cyclone chamber and generally exits via the other end of the cyclone chamber, as opposed to the cyclone chamber illustrated in the embodiment of FIGS. 1 to 18, in which air enters and exits the cyclone chamber via the same end. In the illustrated example, the air inlet 10922 is provided toward the lower end of the cyclone chamber 10913 and the air outlet 10923 is provided toward the upper end of the cyclone chamber 10913, such that air flows into the bottom of the cyclone chamber 10913 and exits at the top of the cyclone chamber 10913. Alternatively, the locations of the air inlet and outlet can be reversed.

Optionally, instead of a vertical configuration, the cyclone bin assembly 10910 and cyclone chamber 10913 can be provided in another orientation, including, for example, as a horizontal cyclone.

Optionally, some or all of the cyclone sidewall 10921 can coincide with portions of the external sidewalls of the cyclone bin assembly 10910 and the dirt collection chamber sidewall 10915. Referring to FIG. 51, in the illustrated embodiment the front portion of the cyclone chamber sidewall 10921 is coincident with the outer sidewall of the cyclone bin assembly 10910, and the rear portion of the cyclone sidewall 10921 helps separate the cyclone chamber 10913 from the dirt collection chamber 10914. This may help reduce the overall size of the cyclone bin assembly 10910. Alternatively, the sidewall 10921 may be distinct from the sidewalls 10915. In alternative embodiments, the cyclone chamber 10913 may include only two dirt outlets 10924, or more than two dirt outlets.

In the illustrated embodiment, the cyclone chamber 10913 includes a first or upper end wall 10937 (FIG. 51) and a second or lower end wall 10943. The upper end wall 10937 is connected to the upper end of the sidewall 10921. In the illustrated example, a juncture 10938 between the end wall 10937 and the side wall 10921 is a relatively sharp corner that does not include any type of angled or radiused surface. In contrast, the lower end wall 10943 meets the lower end of the cyclone sidewall 10921 at a juncture 11005 that includes a curved juncture surface 11006 (see also FIG. 45). The radius 11007 of the curved surface 11006 may be selected based on the radius of the air inlet (e.g. half of the diameter 10934), and optionally may be the selected so that the juncture surface 11006 has the same radius as the air inlet 10922.

The curved juncture surface can be provided as a portion of the sidewall or as a portion of the end wall. In the illustrated embodiment, the curved juncture surface 11006 is provided as part of an insert member 11008 that is provided on the bottom end wall and extends upward into the interior of the cyclone chamber 10913. The insert member also includes an upwardly extending projection member 11009 that extends into the interior of the cyclone chamber and engages the distal end 10930 of the screen (FIG. 51). Together, the vortex finder 10927, screen 10928 and projection member 11009 form a generally continuous internal column member that extends between the first and second end walls 10937 and 10943 of the cyclone chamber 10910. Providing the projection member 11009 may help direct air flow within the cyclone chamber, and may help support and/or stabilize the distal end 10930 of the screen 10928.

Optionally, the juncture 11010 between the end wall 10943 and the projection member 11009 may include a curved surface 11011 (see FIGS. 41 and 44), and preferably is sized so that the surface 11011 has a radius 11012 that is the same as radius 11007. Providing curved surfaces 11006 and 11011 at the junctures between the end wall 10943 and the sidewall 10921, may help reduce backpressure and may

help improve cyclone efficiency. Preferably, the two curved juncture surfaces **11006** and **11011** are separated by a generally flat, planar transition surface **11013**, having a width **11014**. Providing a flat transition surface **11013** may help improve air flow, and/or reduce back pressure to help improve cyclone efficiency.

In the illustrated embodiment, the second end wall **10943** of the cyclone chamber **10913**, and the insert member **11008** provided thereon, is integral with the openable bottom door **10917** that provides the bottom wall of the dirt collection chamber **10914**. In this configuration, opening the door simultaneously opens the cyclone chamber **10913** and the dirt collection chamber **10914** (see for example FIGS. **42** and **43**) for emptying.

In the illustrated embodiment, the dirt outlet **10924** is in the form of a slot having bottom and side edges provided by the cyclone chamber sidewall **10921**, and a top edge provided by the upper end wall **10937**. Alternatively, all four edges of the slot **10924** may be provided by the cyclone chamber sidewall **10921**. The dirt slot **10924** is positioned at the back of the cyclone chamber **10921** and is generally opposite the air inlet **10922**. In the illustrated embodiment, the upper wall **10937** of the cyclone chamber is integral with the upper wall **10916** (FIGS. **41** and **44**) of the dirt collection chamber **10914**.

Optionally, one or more pre-motor filters may be placed in the air flow path between the cyclone bin assembly **10910** and the suction motor **10911**. Alternatively, or in addition, one or more post-motor filters may be provided downstream from the suction motor.

Referring to FIG. **45**, a filter housing construction that may be used by itself or with any other feature disclosed herein is exemplified. In the illustrated embodiment a pre-motor filter chamber or housing **10956** is provided between the upper walls **10937**, **10916** of the cyclone **10913** and dirt collection chambers **10914** and the openable cover **10959**. In this configuration, the bottom wall **10957** of the pre-motor filter chamber **10956** is integral with the upper walls **10937**, **10916** of the cyclone **10913** and dirt collection chambers **10914**, and the upper wall **10958a** and sidewall **10958** of the pre-motor filter chamber **10956** are provided via a filter cartridge housing **11015** (see also FIG. **46**). The filter cartridge housing **11015** is separate from the openable cover **10959**. One or more filters may be positioned within the pre-motor filter chamber to filter fine particles from the air stream exiting the air outlet, before it flows into inlet of the suction motor. The filters may be of any suitable configuration and formed from any suitable materials. In the illustrated embodiment, a foam filter **10960** and a felt filter **10961** (FIG. **30**) are positioned within the pre-motor filter chamber **10956**.

Referring to FIGS. **45-48**, the filter cartridge is a generally dome shaped member that includes an upper wall **10958a** and a sidewall **10958** extending downwardly from the upper wall to surround the pre-motor filters **10960**, **10961**. The pre-motor filters **10960**, **10961** are shaped to fit within the cartridge member **11015**, and when inserted within the cartridge member (FIG. **47**) the downstream side **10965** of the felt filter **10961** forms the bottom surface of the filter cartridge **11015**. When the filter cartridge **11015** is inserted in its use position (FIG. **46**) the downstream side **10965** of the pre-motor filter rests on the support ribs **10962** (see FIG. **47**) on the bottom wall **10957**, and the downstream headspace **10964** (FIG. **45**) is defined between the downstream side **10965** of the filter **10961** and the bottom wall **10957**.

In this embodiment, the upstream headspace **10970** (FIG. **35**) is provided between the upstream side **10968** of the

pre-motor filter **10960** and the upper wall **10958a** of the cartridge housing **11015** (instead of being formed by the cover **10959**). To provide air into the upstream headspace **1970**, the vortex finder **10927** projects upwardly from the bottom wall **10957** and the filters **10960** and **10961** are provided with a corresponding aperture **10972** to receive the vortex finder **10927**. Preferably, a plurality of spacing ribs **11016** (FIG. **48**) are provided on the inner surface of the upper wall **10958a** to keep the upstream surface **10968** of the filter **10960** spaced apart from the inner surface of the upper wall **10958a** to maintain the upstream headspace **10970**.

The lower rim **11017** of the filter cartridge **11015** housing is configured to seal against the bottom wall **10957** (for example via snap fit or by using any type of suitable gasket or sealing member) to provide a generally air tight pre-motor filter chamber **10956**. The sealed chamber **10956** is then covered by openable chamber cover **10959**. As the filter cartridge housing **11015** provides a sufficiently air tight connection to the bottom wall, the chamber cover **10959** need not be air tight. Preferably, at least a portion of both the chamber cover **10959** and the filter cartridge **11015** housing is transparent so that a user can inspect the upstream side **10968** of the pre-motor filter **10960** without having to remove it from the chamber **10956**. Optionally, both the chamber cover **10959** and filter cartridge housing **11015** may be formed from transparent plastic.

When a user wishes to remove, clean, change or otherwise access the pre-motor filter **10960**, **10961** he/she may open the chamber cover **10959** (FIG. **48**) to expose the filter cartridge housing **11015**. The user may then detach the filter cartridge housing **11015** and separate it from the bottom wall **10957**. Preferably, the pre-motor filters **10960**, **10961** are snugly received within the filter cartridge housing **11015** (or otherwise retained therein) so that the filters **10960**, **10961** are removed with the filter cartridge housing **11015** and remain inside the filter cartridge housing **11015** until removed by a user. In this embodiment, the dirty, upstream side **10968** of the filter **10960** remains enclosed by the filter cartridge housing **11015** when separated from the core cleaning unit **11000**, and only the relatively clearer downstream side **10965** of the filter **10961** is exposed. This may help prevent dirt on the upstream side **10968** of the filter **10960** from spilling or from otherwise contacting the user. When at a desired location, for example at a trash receptacle or a sink, a user can grasp the clean, downstream side **10965** of the filter and remove it from the filter cartridge housing **11015**. The upstream side **10968** of the filter can then be cleaned and inspected as desired.

To assist a user, the upper side **1958a** of the filter cartridge housing **11015** may be provided with a grip member, for example the flange **11018** in the illustrated embodiment (FIG. **46**), which may allow a user to firmly grasp and manipulate the filter cartridge housing **11015**. The grip member **11018** may be of any suitable configuration and optionally may be provided on other portions of the filter cartridge housing (for example as a ridge or groove in the sidewall). Alternatively, the filter cartridge housing **11015** need not include a separate grip member.

To help reduce the overall size of the surface cleaning apparatus, in the illustrated embodiment the pre-motor filter chamber **10956**, and the filters therein, is positioned above the cyclone chamber **10913** and covers the upper end of the cyclone chamber **10913**. In this configuration, a plane **10966** (FIG. **44**) containing the foam filter **10960** is generally parallel and spaced above a plane **10977** containing the air outlet **10923** of the cyclone chamber **10913**, and both planes **10966**, **10967** are generally perpendicular to the cyclone

axis **10920**. Arranging the filters **10960**, **10961** in this configuration results in the upstream side of the pre-motor filter (in this example the upper side **10968** of the foam filter **10960**) being spaced further apart from the cyclone chamber **10913** than the downstream side of the pre-motor filter (in this example the lower surface **10965** of the felt filter **10961**). Alternatively, in other embodiments, the pre-motor filter chamber **10956** may cover only a portion of the upper end of the cyclone chamber and/or may be laterally spaced apart from the cyclone chamber.

When the surface cleaning apparatus is in use, air exiting the cyclone chamber **10913** can flow into the upstream head space **10970** via the vortex finder **10927**. Within the upstream headspace **10970** the air can flow laterally across the upstream surface **10968** of the foam filter **10960**, and down through the filters into the downstream head space **10964**. From the downstream head space **10964**, the air can flow to the inlet **10973** of the suction motor via an internal air conduit **10974** (FIG. 44) formed within the body **10901**. In the illustrated embodiment, the internal air conduit **10974** is formed within the main body **10901** and is external the cyclone chamber **10913** and the dirt collection chamber **10914** and is partially bounded by an exterior surface exterior surface of the dirt collection chamber sidewall **10915**. The air conduit **10974** extends generally vertically between the pre-motor filter chamber **10956** and the suction motor **10911**, and is positioned laterally intermediate the suction motor **10911** and the cyclone chamber **10913**. The suction motor **10911** is positioned at an elevation where its air inlet **10973** is vertically between the upper and lower ends of the cyclone chamber **10913**, and the motor axis passes **10926** through the cyclone chamber **10913** and the dirt collection chamber **10914**.

Optionally, the cartridge member **11015** can be provided with a bottom cover **11030** to encase the filters **10960** and **10961** and to provide a self-contained pre-motor filter chamber **10956**. Referring to FIGS. 51 and 52, in such a configuration, the bottom cover **11030** may provide the bottom wall **10957** of the pre-motor filter chamber **10956**, and may be provided with internal ribs **10962** to support the filters **10960**, **10961** and to provide the downstream headspace **10964**. An outlet port **11031** provided in the bottom cover **11030** allows air to exit the cartridge enclosure **11015** and flow into conduit **10974**. Providing a sealed cartridge may help further contain dirt within the cartridge prior to emptying, and may help keep the filters **10960** and **10961** in position.

Referring to FIG. 38, in the illustrated embodiment, handle **10902** has a first or bottom end **10981** that is adjacent the suction motor housing **10912**, a second or upper end **10982** that is spaced above from the lower end **1981** and a grip portion **10980** extending therebetween. When grasping the hand grip portion **10980**, a user's fingers may pass through an opening **10984**.

Referring to FIG. 49, a sectional view of an alternate embodiment cyclone bin assembly portion **12910** of a core cleaning unit **13000** that may be used by itself or with any other feature disclosed herein is exemplified. The cyclone bin assembly **12910** is similar to bin assembly **10910**, and like features are identified using like reference numerals indexed by **2000**. The cyclone bin assembly **12910** is illustrated in isolation with the outer shell, filter cartridge member and the suction motor removed. In this embodiment the cyclone chamber **12913** is flared such that the cross-sectional area taken in a plane **13020** that passes through the air inlet **12922** (toward the bottom of the cyclone chamber **12913**) is smaller than the cross-sectional area taken in a

plane **13021** that passes through the dirt outlet **12924**, and is smaller than the cross-section area of the upper end wall **12937** of the cyclone chamber **12913** (which includes the air outlet **12923**). In this configuration, the cyclone chamber sidewall **12921** includes a vertical portion **13022** and a generally frusto-conical portion **13023** positioned above the vertical portion **13022**. In this embodiment the volume of the cyclone chamber **12913** increases toward the top to the cyclone chamber, which may help improve cyclone efficiency and/or may help dis-entrained dirt exit via the dirt outlet.

Cyclone Bin Assembly

The following is a description of alternate cyclone bin assemblies, which may be used by itself or in any surface cleaning apparatus or in any combination or sub-combination with any other feature or features disclosed herein.

Referring to FIG. 50, a sectional view of an alternate embodiment cyclone bin assembly **14910** portion of the core cleaning unit **15000** that may be used by itself or with any other feature disclosed herein is exemplified. The cyclone bin assembly **14910** is similar to cyclone bin assembly **10910**, and like elements are represented using analogous reference numbers indexed by **4000**. The cyclone bin assembly **14910** is illustrated in isolation with the outer shell, filter cartridge member and the suction motor removed. In this embodiment the cyclone chamber **14913** is tapered such that the cross-sectional area taken in a plane **15020** that passes through the air inlet **14922** (toward the bottom of the cyclone chamber **14913**) is larger than the cross-sectional area taken in a plane **15021** that passes through the dirt outlet **14924**, and is larger than the cross-section area of the upper end wall **14937** of the cyclone chamber **14913** (which includes the air outlet **14923**). In this configuration, the cyclone chamber sidewall **14921** includes a vertical portion **15022** and a generally inwardly-tapering frusto-conical portion **15023** positioned above the vertical portion. In this embodiment the volume of the cyclone chamber **14913** decreases toward the top to the cyclone chamber, which may help improve cyclone efficiency and/or may help dis-entrained dirt exit via the dirt outlet.

Referring to FIG. 53, a sectional view of an alternate embodiment cyclone bin assembly portion **16910** of a core cleaning unit **17000** that may be used by itself or with any other feature disclosed herein is exemplified. The cyclone bin assembly **16910** is similar to cyclone bin assembly **10910**, and like elements are represented using analogous reference numbers indexed by **6000**. In this Figure, a pre-motor filter housing construction that may be used by itself or with any other feature disclosed herein is exemplified.

In the illustrated embodiment, a pre-motor filter chamber or housing **16956** is provided between the upper walls **16937**, **16916** of the cyclone and dirt collection chambers **16913**, **16914** and the openable cover (not shown). In this configuration, the bottom wall **16957** of the pre-motor filter chamber **10956** is integral with the upper walls **10937**, **10916** of the cyclone **10913** and dirt collection chambers **10914**, and the upper wall **10958a** and sidewall **10958** of the pre-motor filter chamber **10956** are provided via a filter cartridge housing **17015**. One or more filters may be positioned within the pre-motor filter chamber to filter fine particles from the air stream exiting the air outlet, before it flows into inlet of the suction motor. The filters may be of any suitable configuration and formed from any suitable materials. In the illustrated embodiment, a foam filter **16960** and a felt filter **16961** are positioned within the pre-motor filter chamber **16956**.

The pre-motor filters **16960**, **16961** are shaped to fit within the cartridge member **17015**, and when inserted within the cartridge member the upstream side **16968** of the felt filter **16961** forms the bottom surface of the filter cartridge **11015**. When the filter cartridge **17015** is inserted in its use position (as shown) the upstream side **16968** of the pre-motor filter rests on the support ribs **16962** on the bottom wall **16957**, and the upstream headspace **16970** is defined between the upstream side **16968** of the filter **16960** and the bottom wall **16957**.

In this embodiment, the downstream headspace **16964** is provided between the downstream side **16965** of the pre-motor filter **16961** and the upper wall **10958a** of the cartridge housing **11015**. Optionally, a plurality of spacing ribs **17016** can be provided on the inner surface of the upper wall **16958a** to keep the downstream surface **16965** of the filter **16961** spaced apart from the inner surface of the upper wall **16958a** to maintain the downstream headspace **16964**.

When the cyclone bin assembly **16910** is in use the upstream side **16968** of the filter **16960** may become soiled and/or partially blocked by dust and other relatively fine debris that is carried out of the cyclone chamber **16913**. If the upstream side **16968** becomes sufficiently blocked, air-flow through the filter **16960** may be compromised and efficiency of the surface cleaning apparatus may decrease.

One method of cleaning the upstream side **16968** of the filter **16960** is for a user to remove the filter **16960** as described above, clean the surface **16968** and replace the filter **16960** within the pre-motor filter chamber **16956**. Alternatively, instead of removing the filter **16960** from the pre-motor filter chamber **16956**, the surface cyclone bin assembly **16910** may be configured to allow the filter **16960**, particularly the upstream side **16986**, to be cleaned in situ, without removing the filter **16960** from the pre-motor filter chamber **16956**. Dirt and debris may be extracted from the upstream side **16968** using any suitable mechanism, including, for example, banging or tapping the sides of the pre-motor filter chamber **16956** to dislodge the dirt and using a mechanical and/or electro-mechanical mechanism to help dislodge the debris. Examples of such mechanisms may include, for example, a scraper or other mechanical member that contacts and cleans the surface **16968** and a shaker or beater type of mechanism that can shake the filter **16960** to help dislodge the debris.

Optionally, the pre-motor filter chamber **16956** may be configured to receive fine dirt and debris from the upstream side **16968** and direct the debris into a fine particle collection chamber or pre-motor filter dirt chamber that can collect the dislodged debris. The fine particle collection chamber may be a portion of the primary dirt collection chamber **16914**, or may be provided as a separate chamber.

In the illustrated embodiment, the cyclone bin assembly **16910** includes a two pre-motor filter dirt chambers **17040a** and **17040b** for receiving debris **17041** that is dislodged from the upstream upside **16968** of filter **16960**. In the illustrated embodiment, the first dirt chamber **17040a** is located within an extension member **17042**, which is inside the cyclone chamber **16913**. In this configuration, there is no communication between the first dirt chamber **17040a** and the dirt chamber **16914**, nor do they share any walls or components in common.

The second dirt chamber **17040b** is provided outside and adjacent the dirt chamber. The second dirt chamber **17040b** is partially bounded by the sidewall **16915** of the primary dirt collection chamber **16914**, but is external the chamber **16914** and includes a sidewall **17043**. The second dirt collection chamber **17040b** has a bottom wall **17044** that is

pivotaly connected to the cyclone bin assembly **16910**. The bottom wall **17044** can be opened and closed independently of the bottom walls **16917** and **16943** of the dirt collection chamber **16914** and cyclone chamber **16913** respectively.

In the illustrated example, the bottom wall **16957** of the pre-motor filter chamber **16956** (which is coincident with the upper wall **39** of the cyclone chamber **10** in this example) is inclined from left to right as illustrated. Sloping the wall **16957** in this manner may help guide the debris **17041** that falls from the left side of the filter **16960** (as illustrated) toward the air outlet **16923**, and may guide debris that is positioned to the right of the air outlet **16923** (as illustrated) toward to second dirt chamber **17040b**. When the air flow through the cyclone chamber **16913** is off (i.e. when the cyclone bin assembly **16910** is removed and/or when the surface cleaning apparatus is off), some of the debris **17041** may fall downwardly though the vortex finder **16927**, through air outlet **16923**, pass through the interior of the screen **16928** and fall into the dirt chamber **17040a**. Because the dirt chamber **17040a** is positioned below the air flow openings in the screen **16928** it may be a relatively low air flow region when the surface cleaning apparatus is in use. This may allow debris **17041** that has accumulated dirt chamber **17041** to remain in the dirt chamber **17040a** if the surface cleaning apparatus is used prior to emptying the dirt chamber **17040a**, as it is unlikely that the debris **17041** will be re-entrained in the air flowing into the screen **16928** and upwardly though the air outlet **16923**.

Similarly, in the absence of strong air flow, some of the debris **17041** may collect at the bottom of dirt chamber **17040b**. Like chamber **17040a**, chamber **17040b** is provided below and generally outside the primary air flow path through the cyclone bin assembly **16910**. This may allow debris **17041** to remain contained in dirt chamber **17040b** if the cyclone bin assembly **16910** is operated before emptying dirt chamber **17040b**.

The dirt chamber **17040a** includes a sidewall **17046** and a bottom wall **17047**. The top of the chamber **17040a** is open to receive the debris **17041**. In the illustrated embodiment the bottom wall **17047** of the dirt chamber **17040a** is a cap member that is distinct from the floor **16943** of the cyclone chamber **16913**. In this configuration, opening the door **16943** simultaneously opens the cyclone chamber **16913**, the dirt chamber **16914** but does not automatically open the pre-motor filter dirt chamber **17040a**. To empty the dirt chamber **17040a**, the user can remove the bottom wall **17047**. This allows a user to decide when to empty the dirt chamber **17040a** independently from the cyclone chamber **16913** and the dirt chamber **16914**. Alternatively, the dirt chamber **17040a** need not include a separate bottom wall member **17047**, and the bottom of the dirt chamber **17040a** can be sealed by the bottom wall **16943** of the cyclone chamber **16913**. In such a configuration, the dirt chamber **17040a** would be opened with the cyclone chamber **16913**. The bottom wall **17044** is not operatively connected to the bottom walls **16917** and **16943**, and therefore chamber **17040b** is openable independently from dirt chamber **17040a**, cyclone chamber **16913** and dirt chamber **16914**.

Optionally, the cyclone bin assembly **16910** may include an additional dirt collection chamber that is positioned within the pre-motor filter chamber **16956**. Referring to FIG. **54**, the cyclone bin assembly **16910** is illustrated containing a removable dirt collection chamber **17040c** positioned within the pre-motor filter chamber **16956**. The dirt collection chamber **17040c** is a cup-like member that can collect a portion of the debris **17041** that falls from the filter **16960**. Providing a third chamber **17040c** may help reduce the

amount of debris that accumulates within chambers **7040a** and **17040b**. In the illustrated configuration, the dirt chamber **17040c** is not emptyable like chambers **17040a** and **17040b** and does not include any type of openable door. Instead, the dirt chamber **17040c** is removably seated within the pre-motor filter chamber **16956** and can be removed for emptying when the filters **16960** and **16961** are removed by the user.

In these examples, debris **17041** may be dislodged from the filter **16960** by shaking or banging the cyclone bin assembly **16910**. Alternatively, a filter cleaning mechanism can be included within the pre-motor filter chamber **16956**.

Referring to FIG. **55**, another embodiment of a cyclone bin assembly **18910** is exemplified having an example of a filter cleaning mechanism **19060**, which may be used in combination with any other suitable cyclone bin assembly described herein. In the illustrated embodiment, the filter cleaning mechanism **19060** is provided in the form of a rotating sweeper apparatus **19061** that includes a pair of sweeper arms **19062** that can scrape the upstream surface **18968** of the filter **18960**. The sweeper arms **19062** may be of any suitable configuration, and may be formed from any suitable material including, for example, plastic and metal.

The sweeper arms **19062** are connected to a central hub **19063** which is mounted to shaft **19064**. Shaft **19065** is driven by electric motor **19065** and rotates about axis **19066**. The motor **19065** is mounted to one of the support ribs **18962** within the upstream head space **18970**. Additional ribs surrounding the filter cleaning mechanism **19060** may include cut-outs to allow the sweeper arms **19062** to pass. Alternatively, instead of completing full revolutions the motor **19065** may be configured to oscillate back and forth.

Providing the filter cleaning mechanism in the upstream headspace **18970** may be advantageous as it allows the sweeper arms **19062** to directly engage the upstream surface **18968**.

The motor **19065** may be supplied with power from any suitable source, including the external power source and/or an onboard power storage device, such as batteries. Providing batteries may be advantageous as it may allow the filter cleaning mechanism **19069** to be operated when the surface cleaning apparatus is unplugged.

Alternatively, instead of providing a motor **19065**, the shaft **19064** may be rotatably or pivotally supported by bearings or bushings within the pre-motor filter chamber **18956**, but need not have a drive mechanism. In such a configuration, the sweeper arms **19062** may be moved across the surface **18968** of the filter **18960** when a user shakes or bangs the outside of the cyclone bin assembly **18910**. In this configuration, the filter cleaning mechanism **19060** may amplify the user's input force and use that force to clean the filter **18960**. In yet another alternative configuration, an external crank or actuator may be provided to allow a user to manually rotate the shaft **19064** and sweeper arms **19062**.

Also of note in this embodiment, the bottom walls **19044** and **19047** of the pre-motor filter dirt chambers **19070b** and **19070a** are both integral with walls **18917** and **18943**. In this configuration, the pre-motor filter chambers **19040a** and **19040b**, the cyclone chamber **18913** and dirt chamber **18914** are simultaneously openable.

Referring to FIG. **56**, the cyclone bin assembly **18910** is illustrated containing another embodiment of a filter cleaning mechanism **19060**, which may be used in isolation or in combination with any other features herein. In this embodiment, the filter cleaning mechanism **19060** includes a motor **19065** that is mounted to the upper wall **18958** of the

cartridge housing **19015** and is positioned within the downstream headspace **18964**. The motor **19065** includes an output shaft **19064** that is coupled to an eccentrically mounted beating member **19070**. The beating member **19070** can be formed from any suitable material (e.g. plastic and metal) and can be of any suitable shape.

In the illustrated embodiment the beating member is a generally cylindrical member mounted eccentrically on the shaft **19064**. As the shaft rotates the beating member **19070** will periodically impact the downstream side **18965** of filter **18961**. The impact on the surface of filter **18961** may produce vibrations in filter **18961**, and the vibrations may be transferred to filter **18960**. Vibrations in filter **18960** may tend to dislodge debris from the upstream side **18968** of the filter **18960**, and into the dirt collection chambers **19040a** and **19040b**. The motor **19065** may be powered using any suitable source as described herein.

What has been described above has been intended to be illustrative of the invention and non-limiting and it will be understood by persons skilled in the art that other variants and modifications may be made without departing from the scope of the invention as defined in the claims appended hereto. The scope of the claims should not be limited by the preferred embodiments and examples, but should be given the broadest interpretation consistent with the description as a whole.

What is claimed is:

1. A surface cleaning apparatus comprising:

- (a) an air treatment member having a first end, a longitudinally spaced apart second end, a longitudinal axis extending between the first and second opposed ends, an air inlet and an air outlet comprising an outlet conduit;
- (b) an air flow path extending from a dirty air inlet to a clean air outlet and including a suction motor and the air treatment member;
- (c) a pre-motor filter positioned in the air flow path downstream from the air treatment member, the pre-motor filter comprising a filter media having an upstream surface through which air enters the filter media and a downstream surface through which air exits the filter media, the downstream surface is spaced apart from the upstream surface in a flow direction as air passes through the pre-motor filter; and,
- (d) an agitation member positioned downstream of the pre-motor filter and an agitation motor having a drive shaft, the agitation member is eccentrically mounted to the drive shaft whereby the agitation member periodically impacts the pre-motor filter as the drive shaft rotates to impart a force in a direction generally parallel to the flow direction, wherein the agitation member is solely supported by the drive shaft.

2. The surface cleaning apparatus of claim 1 wherein the downstream surface is planar and wherein the drive shaft extends in a direction that is generally parallel to the downstream planar surface.

3. The surface cleaning apparatus of claim 1, wherein the agitation motor is on a downstream side of the pre-motor filter.

4. The surface cleaning apparatus of claim 1 further comprising an agitation motor operatively connected to the agitation member and the agitation member is eccentrically mounted to the agitation motor.

5. The surface cleaning apparatus of claim 1, wherein the air treatment member comprises a cyclone chamber having a cyclone axis of rotation, the pre-motor filter overlies the

cyclone chamber whereby the agitation member imparts the force in the longitudinal axial direction.

6. The surface cleaning apparatus of claim 1, wherein the pre-motor filter comprises a foam filter.

7. The surface cleaning apparatus of claim 2, wherein the air treatment member comprises a cyclone chamber having a cyclone axis of rotation, the pre-motor filter overlies the cyclone chamber whereby the agitation member imparts the force in the longitudinal axial direction.

8. The surface cleaning apparatus of claim 7, wherein the pre-motor filter comprises a foam filter.

9. The surface cleaning apparatus of claim 6, wherein the agitation member imparts the force to the downstream surface of the filter media.

10. A surface cleaning apparatus comprising:

(a) an air treatment member having a first end, a longitudinally spaced apart second end, an air inlet and an air outlet comprising an outlet conduit;

(b) an air flow path extending from a dirty air inlet to a clean air outlet and including a suction motor and the air treatment member;

(c) a pre-motor filter positioned in the air flow path downstream from the air treatment member, the pre-motor filter comprising a filter media having an upstream surface through which air enters the filter media and a downstream surface through which air exits the filter media, the downstream surface is generally parallel to the upstream surface and spaced apart from the upstream surface in a spacing direction that is generally perpendicular to each of the upstream and downstream surfaces; and,

(d) an agitation member positioned downstream of the pre-motor filter and an agitation motor having a drive shaft, the agitation member is eccentrically mounted to the drive shaft whereby the agitation member impacts the filter media in an impact direction that is generally parallel to the spacing direction as the agitation member rotates about the axis of the drive shaft of the agitation motor.

11. The surface cleaning apparatus of claim 10, wherein the filter media comprises a foam filter.

12. The surface cleaning apparatus of claim 10, wherein the agitation member impacts the downstream surface of the filter media.

13. The surface cleaning apparatus of claim 10, wherein the drive shaft extends in a direction that is generally perpendicular to the spacing direction.

14. The surface cleaning apparatus of claim 10, wherein the agitation motor is on a downstream side of the pre-motor filter.

15. The surface cleaning apparatus of claim 10, wherein the agitation member is eccentrically mounted to an agitation drive member.

16. The surface cleaning apparatus of claim 10 further comprising an agitation motor operatively connected to the agitation member and the agitation member is eccentrically mounted to the agitation motor.

17. A surface cleaning apparatus comprising:

(a) an air treatment member comprising a cyclone having a first end, an axially spaced apart second end defining an axial direction, an air inlet and an air outlet comprising an outlet conduit;

(b) an air flow path extending from a dirty air inlet to a clean air outlet and including a suction motor and the air treatment member;

(c) a pre-motor filter positioned in the air flow path downstream from the air treatment member, the pre-motor filter comprising a filter media having an upstream surface through which air enters the filter media and a downstream surface through which air exits the filter media, the downstream surface is spaced apart from the upstream surface in the axial direction of the cyclone; and,

(d) an agitation member positioned downstream of the pre-motor filter and an agitation motor having a drive shaft, the agitation member is eccentrically mounted to the drive shaft whereby the agitation member periodically impacts the pre-motor filter as the drive shaft rotates to impart a force to the pre-motor filter generally in the axial direction, wherein the agitation member is solely supported by the drive shaft.

18. The surface cleaning apparatus of claim 17, wherein the agitation member impacts the downstream surface of the filter media.

19. The surface cleaning apparatus of claim 17, wherein the downstream surface generally defines a plane, wherein the drive shaft extends in a direction that is generally parallel to the plane.
